QUESTIONS IN PROCTOLOGY

CHAIRMAN'S ADDRESS

CURTICE ROSSER, M.D.

Professor of Proctology Baylor University School of Medicine
DALLAS, TEXAS

From time immemorial, surgery and surgeons have been concerned predominantly with the practical application of acquired knowledge and skill. Because surgery has developed primarily as an art, surgical literature from the earliest eras has recorded innumerable variants of two fundamental themes—amputation and drainage. A new hemostatic, a new approach, a modified technic to facilitate removal of an organ or evacuation of pathologic material—each serves today as it has in the past to adorn the page and dignify the rostrum.

Moreover, the surgeon, however great his respect for tradition, has been preeminently an individualist, often showing complete disregard for the immediately previous technical schools, and it is perhaps for this reason that, in general, surgical procedures present a somewhat rhythmic reiteration of previous stages of opinion sufficient to suggest that currently fashionable cycles occur here as they do in more mundane fields.

The present-day proctologist excises a fistulous tract whereas two short decades ago he incised it and three decades ago used a seton or caustic, without special thought of the fact that, 400 years before Christ, Hippocrates presented a choice of the knife, the horse-hair seton or the escharotic covered tent for the identical lesion. During our own lifetime the angiotribe, the cautery and the scalpel have each crossed the stage as principal actors in the operation of hemorrhoidectomy as they have crossed and recrossed it during the centuries since Hippocrates described the destruction of piles by pressure, by fire and by cutting.

Proctology, a field long practically abandoned by the general profession to the itinerant and the irregular, has been in recent years to large measure reclaimed to orthodox medicine through increasing realization of its import in the general medical scheme, by the evolution of undergraduate instruction in anorectal disorders and by a definite demand on the part of general practitioners that disorders so widespread in their clientele be the benefit of careful and scientific consideration.

Certain very definite responsibilities arose from the novel renaissance as an orthodox specialty of a hitherto

neglected phase of medicine. Accurate diagnosis became essential and the Hanes position, electrically lighted colonoscope and the perfected barium ray have made it possible. From the general surgeon has been appropriated a rational operative technic which he himself refused to apply to this one field—comprising proper exposure, fortunately facilitated by the new block anesthetics, complete but careful dissection of diseased tissue with whatever instrument would be appropriate in any other body locality, hemostasis with the absorbable suture or coagulating current of today rather than the cautery of another era, and the same attention to the postoperative wound granted to similar wounds in distant portions of the body.

Proctologic surgery has thus rightly concerned itself with the ceremonies associated with the art of surgery, but its future progress will be indexed by its solution of questions connected with the science as well as the craft of our domain.

Any number of interesting problems and adjustments remain for systematic investigation. Among the more important are several phases of comparative surgical pathology applicable to this field and a consideration of the venereal problem as it involves the lower bowel. These are selected to serve as illustrations of the questions referred to and for the further reason that their discussion permits a revision and elaboration of subjects which it has heretofore been my privilege to present before this body.

Variations in disease due to racial peculiarities continue to offer a field of investigation no longer limited in its interest to the Southern practitioner.

Nine years ago before this section I called attention to the role enacted in rectal pathologic changes in the Negro by that racial peculiarity termed the fibroplastic diathesis—the inherent ethnic predisposition to develop adult connective tissue in excess in response to trauma of any type.¹ From the analysis of cases presented at that time, it was indicated that rectal disease in general is equally prevalent in the Caucasian and in the Negro, that cancer, pruritus and fissure are less common in the Negro, while the inflammatory lesion, including fistula, is more often found in the Negro. Benign rectal stricture, accompanied by other manifestations of the fibroplastic diathesis, was eleven times as frequent in the Negro, while hemorrhoids occurred only half as often. In addition microscopic studies of a series of excised hemorrhoids from both races indicated that fibrosis is the dominant feature of the Negro hemorrhoid which suggests that the varicosity effaces itself in the Negro.

In the discussion that followed Dr Rudolph Matas, whose splendid studies on comparative surgical pathol-

Owing to lack of space this article has been abbreviated in THE JOURNAL by the omission of figure 1. The complete article appears in the author's reprints.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 15, 1933.

ogy published twenty-eight years before had served as inspiration for my own work, summarized the experience of the division of anorectal diseases of Charity Hospital, New Orleans, for the decennium 1914 to 1923, inclusive. Except that the incidence of cancer in Negroes in his series was higher, the statistics were in general agreement with those reported from Dallas. Dr. Matas had not, however, convinced himself that the fibroplastic reaction of the Negro was the underlying cause of the higher incidence of nonmalignant rectal stricture in the race, believing that the greater frequency with which the Negro harbors the spirochete and the tubercle bacillus accounted for the discrepancy.

That neither tuberculosis nor syphilis is the prime cause of the rectal ulceration which eventuates in benign obliterating stenosis is the present considered opinion of many others besides myself. That a reaction very similar to keloid formation of the skin occurs in and under the rectal mucosa has remained my belief, a belief augmented by universal detection in the ulcerated Negro rectum of characteristic firm submucosal nodules before the stage of or separate from the constricting band, nodules which have a similar etiology, feel and histopathology to keloid and which are not found under similar conditions in white patients.

The comparative reports of Matas from Charity Hospital were supplemented in 1928 by Dr. Jeff Miller² who summarized the statistics of the years 1917-1926 with special reference to gynecologic disorders. Among his figures one observes the fact that uterine fibroids occurred in 23.5 per cent of Negro gynecologic admissions as opposed to 3.4 per cent in white persons, that 94.4 per cent of the cases of elephantiasis of the vulva were in Negro women and that 67.7 per cent of 164 fistulas occurred in the Negro race.

Pearl's³ statistics from 6,670 autopsies in the Johns Hopkins Hospital show that in this group malignant tumors occur from two to three times more frequently relatively among white persons than they do among Negro persons, this racial difference being much more marked relatively for sarcoma and other noncarcinomatous groups. The author states that other trustworthy data show that in general malignant new growths occur with considerably greater frequency in the white race in the United States, which may indicate in the Negro a lower susceptibility of truly genetic racial origin.

Dr. Hoffman,⁴ who has had a long interest in this question, published in 1931 an extremely interesting compendium of statistics from this country and Africa bearing on the comparative frequency of cancer in the white and Negro races, his own conclusion being that malignancy is highly uncommon in the Negro living in Africa and was extremely rare in our slave population but that this partial exemption is being lost through change in living conditions and perhaps also through white intermixture—the cancer mortality of our American Negro population tending more and more during the last thirty years to approach the corresponding cancer death rate of the white population. Of ninety-three cases of rectal cancer coming under my observation, 65 per cent were in Negroes, a decided increase over the incidence formerly reported. All were adenocarcinomas and four developed in old fistulous tracts.

Seven years ago, when I⁵ brought to the notice of this section the anorectal phase of the venereal problem, syphilis was still regarded as a not uncommon fact and the high incidence of gonorrhea was first being appreciated. I now have every reason to retract the impression reported at that time that approximately one fourth of inflammatory rectal strictures were syphilitic in origin, as my own observations have confirmed those of others that manifestations of tertiary syphilis are quite rare in the anorectum.

The perianal chancre is seen more commonly in crowded centers; my experience includes only three instances. Chancroid, however, is sufficiently common to be considered in the differential diagnosis of an anal ulcer. The typical lesions are multiple, the two commissures being favorite sites, the ulcer is ragged and undermined, induration is absent, a thin purulent discharge is seen on the ulcer surface and the predominant symptom is severe constant pain aggravated by the slightest touch (fig. 1).

The larger group of these cases have been seen in medical school dispensaries, however. I find ten instances recorded in my private files since 1925. Of these, eight were young white women and in two of these cases the infection was an unwelcome and at first unsuspected invader of postoperative wounds. The diagnosis must be confirmed by auto-inoculation and elimination of syphilis, as the microscopic picture is not helpful and smears seldom reveal the Dreyer organism. Before 1928 these patients were placed in the hospital, the anal sphincter was severed to relieve the characteristic intolerable pain, and the acids and escharotics which are still, I believe, in use among urologists were applied to the lesion after local cocaineization. Since 1928, all patients after confirmation of the diagnosis have been placed on intravenous mercurochrome and no lesion observed in my private practice or dispensary service has failed to heal rapidly and completely as the result of this single therapy.

Rectal gonorrhea was first described by Hecker, a professor in Erfurt in 1789. Jullien, about 1886, reported additional studies and described a triad of findings he thought essential to confirm the diagnosis, purulent discharge, broad anal ulcer and condyloma. Neisser, at the second International Congress of Dermatologists in Vienna in 1892, stressed the importance of this condition and continental writers have continued to discuss its incidence and therapy since. In the United States the disease has continued to be regarded as a rare and self-limited complication requiring no attention except for a short period of palliation in those cases (the minority) in which unusually severe acute local reactions enforce it.

Anal gonorrhea, which invades the rectum only as a secondary process, is a rare disease in the male; it is, however, a quite common concomitant of urethral and cervical infection in the female. Adherence to the diagnostic criteria of Jullien has been responsible for the failure to recognize the condition as a very small percentage of these patients present rhagades, external ulcers and condylomas.

Hayes⁶ in 1929, reviewed the literature on this subject, which already suggested wide prevalence called attention to the ease with which the disease could be overlooked, and emphasized the occurrence of such

complications as stricture, abscess, fistula, condyloma and polypoid rectal excrescence.

The most important contributions to this discussion since that time have been in the German medical prints. There has been a substantial agreement that the incidence is high, that it is possible for the organism to remain in the rectum with unabated virulence for a long period and that rectal inoculation in women usually occurs during defecation when the vaginal secretion is forced out on an everted anal mucosa. On the other hand, there is no agreement found concerning the tissues in which the organism embeds itself after the acute phase, and the treatment advocated is generally vague and nonspecific consisting of suppositories, large lavages and application of silver nitrate solutions to large areas of the rectal mucosa.

Schiffman,⁷ in 1929, reported that in a series of 121 women with gonorrhea, 66 per cent had a rectal infection, 15 of 31 female children had rectal gonorrhea. Temesvary⁸ studied 1,182 gonorrheal women patients seen over an eight year period in a Budapest maternity clinic and 22.1 per cent were found to have the organism implanted in the rectum. Of 256 girl children, 74 were contaminated. The greatest incidence was between 16 and 30 years. Klovekorn⁹ reported from the dispensaries of the university of Bonn, stating that in 1925 rectal involvement was discovered in 24 of 100 women and that in 1930 the percentage was 64.4 per cent. Dahmen,¹⁰ in 1932, stated that, in the examination of gonorrheal patients at a Berlin municipal station serving tramps and homeless women, 41.2 per cent were found to have rectal gonorrhea, at another station where the patients were from a somewhat higher stratum the incidence was 25 per cent.

Muhlfordt¹¹ reported a case in which virulent organisms were found in the rectum two and one-half years after eradication of the primary infection, and Bickel and Abraham's report¹² suggests that the rectum may harbor virulent gonococci for more than ten years after genital infection has disappeared.

In the acute stages the gonococcus would seem to obtain a parasitic dissemination in and on the rectal mucosa. The proctoscopic appearance in early and subacute stages has been described as including a soft, reddened swollen mucosa in the upper anal canal and lower two or three inches of the rectum, with flecks of pus and occasionally punctate hemorrhage. Actual ulceration of the rectal mucosa occurs only in late neglected cases, more especially in the Negro race.

The rectal dispensaries of Baylor University Medical School and of the City-County Hospital of Dallas have treated several hundred cases of gonorrhea during the past ten years (including cases of inflammatory proctitis obliterans accepted by many as a late sequela¹³). Because outpatients especially those of the Negro race, are seen in only the latest stages of the disease and frequently disappear on slight improvement before observations can be completed it is believed that for the purpose of this discussion a brief analysis of twenty-

six cases taken from my office files of the past five years will better illustrate certain phases of the subject from the angle of private practice.

Twenty-four of these patients were white women ten of whom were unmarried.

Of the twenty-four women patients seven were unaware of the presence of cervical or urethral infection, reporting for examination because of rectal symptoms alone. It is interesting to note that every one of these on examination was found to have an anterior infection, demonstrated by finding the gonococcus in the cervix or urethra.

A married woman, aged 28, who three years and seven months before had been found to have an anal infection, was on reexamination found to have retained the organism during that period in the rectum. Smears from the vagina had remained negative during the interim. The clinical virulence of the organism was not ascertainable although cryptitis with mucopurulent discharge was still present.

The following complications were found in this series, developing at various stages of the disease:

Persistent hemorrhoids, one. Removal was required before smears became negative.

Acuminate condyloma, one.

Submucous abscess, one.

Incomplete fistula, one (a deep infected anterior crypt with recurrent swelling and discharge).

Polypoid granulation, one found at the crypt openings.

Anal ulcer, one (a broad granulating ulcer at the dentate line, remains of a posterior infected crypt).

Abscess, then fistula, six. The tracts uniformly led to infected anal crypts and in several the organism was demonstrated in abscess pus.

In the last ten cases the complication was due to persistent infection in the anal crypts. In other words, in 38 per cent of these patients it was demonstrated that cryptitis is a significant factor in the syndrome under discussion.

Free drainage of pus from crypts was observed in a number of instances and the swollen red membrane of the lower two inches of the rectum was interpreted as being the result of a constant purulent discharge from the anal valves deposited in this immediately adjacent tissue. No cases of rectal ulceration were seen in this group, but this sequela occurs frequently in clinic patients as the result of secondary infection of this constantly contaminated mucosa.

Stricture is frequently seen in Negroes because of their fibroplastic diathesis entering the picture when ulcers heal. It was not observed in this group, but I have had the opportunity of observing four typical postgonorrheal stenoses in white women in past years.

My conviction that the anal crypts serve as reservoirs of infection in anal gonorrhea first expressed before this section in 1926, is based on the frequency of observed crypt infection and its direct sequelae and on the necessity to postulate a focus analogous to the urethral glands, prostate and other parts in chronic gonorrhea of the conventional type.

If the anal canal, more especially, the anal crypts are primarily involved in this disease, and if the condition involves changes only in the lowest portion of the rectum and then purely as a secondary manifestation some modification of the present widespread practice of constantly introducing large amounts of irrigating fluids and silver nitrate solutions to the entire rectum and lower sigmoid is essential. These measures encourage a higher dissemination of the process and

in the case of silver nitrate applications to the entire rectal mucosa, lower the resistance of this surface

In the acute stage, rest in bed, hot sitz baths, a bland diet smoothed additionally by small amounts of liquid petrolatum and the use of a very small bland anal douche with a bulb syringe, as suggested by Hayes,⁶ will allay pain

Fig 2—Crypt hook, crypt irrigator and syringe used in the treatment of gonorrheal anal cryptitis

When the tenesmus and local discomfort are abated, the logical procedure is to investigate the lower bowel, using a small anoscope, and direct the curative portion of the treatment to the infected anal canal.

The crypts will be found to show deepening and marginal reddening, and on slight pressure a drop of pus is expressed. In this subacute stage it is my practice to irrigate the crypts gently, using a device which I constructed by bending a flexible sinus irrigator to the proper "shepherd's crook" angle and attaching it to a control syringe (fig 2). A small cotton tampon thoroughly impregnated with a mild antiseptic in an oil base is then inserted in the anal canal in contact with the crypts and the mucosa adjacent. The patient is instructed to continue the small bland anal douche.

When the condition enters the chronic stage, the crypt cavities are stimulated by the application of a weak solution of silver nitrate after being cleansed by irrigation (fig 3).

When persistent drainage and increasing depth in one or more crypts indicate that abscess impends, I believe it entirely proper to excise the infected outer surface of the crypt to prevent this very frequent complication, as gonorrheal abscess almost uniformly produces fistula. This should not be done in the acute stage.

Needless to say, the examination and the various steps of treatment can be done satisfactorily only under direct vision through the anoscope. The decision that the process is eradicated is based on obtaining three negative smears from the crypts one week apart.

The mass of recent literature in connection with the "anorectal phase" of the "fourth venereal disease," the manifestations of which are apparently as protean as are the designations under which it is described, makes it impossible to disregard the possibility that some obliterating inflammatory rectal strictures, particularly when accompanied by perianal elephantiasis and pelvic rectal sinus, must be attributed to this disease.

Sulzberger and Wise¹⁴ state that several cases of stricture in Negro women were tested with the Frei antigen with a positive result. DeWolf and Van Cleave,¹⁵ in testing 1,010 individuals, obtained 58 positives, of which three were cases of rectal inflammation and stricture, while Lutz¹⁶ is of the opinion that the "formerly generally accepted theory that inflammatory strictures of the rectum are primarily of a gonorrheal, tuberculous or syphilitic origin must be abandoned," as a "large number" of these strictures can be proved due to lymphogranuloma inguinale. Moreover, Lohe and Rosenfield¹⁷ claim the successful transmission of material from patients with the anorectal syndrome to the brains of monkeys followed by the production of positive skin reactions with monkey brain antigen in patients with the disease.

The contention of those who maintain that inflammatory stenosis, perianal elephantiasis and high rectal sinus are universally specific, infectious, late forms of lymphopathia venerea is apparently based on the theory that the original lesion occurs on the cervix or in the

Fig 3—Anal crypts showing method of introducing weak solutions of silver nitrate after acute stage has passed

vault of the vagina in women, the infection being transmitted to the deep pelvic lymph nodes and by retro-

grade transportation carried to the periphery to produce elephantiasis, ulceration and, when scarring occurs, stricture. This concept serves, of course, as an explanation of the known increased incidence of stricture in the female. In my own work an attempt is being made to check the incidence of positive Frei tests in the presence of the syndrome under discussion, while the results do not as yet present the unanimity which the enthusiasm of many proponents would lead one to expect, I am keeping an open mind. Lehman and Pipkin of San Antonio¹⁸ tested some 200 cases and obtained only two positive Frei tests from a number presenting inflammatory rectal stricture.

I feel that it is quite possible that this disease plays a definite part in the production of chronic inflammatory lesions of the anorectum, I would suggest, however, that complete abandonment of all previous theories is premature from the evidence. The primary lesion is presumed rather than demonstrated because of its small size and evanescence and no culturable organism has been discovered.¹⁵ The histologic picture is neither typical nor pathognomonic, especially is this true in lesions other than bubo.¹⁴ The antigen of Frei is not entirely satisfactory, being sterilized whole pus. Moreover, the presence of a positive Frei reaction in the absence of specific or pathognomonic local histologic changes is not conclusive per se that the rectal lesion in question is caused by lymphopathia venerea, it was on evidence as intangible that inflammatory stricture was charged to syphilis for so many years.

METABOLIC AND THERAPEUTIC STUDIES IN THE MYOPATHIES

WITH SPECIAL REFERENCE TO GLYCINE
ADMINISTRATION

MEYER M HARRIS, MD
AND
ERWIN BRAND PH D
NEW YORK

Although general attention has been directed to the myopathies since Aran's¹ communication published in 1850 and much has been written regarding them, our insight into the pathogenesis of this group of diseases has remained rather superficial and controversial.

Oppenheim² in summing up his communication on the myopathies before the Seventeenth International Congress of Medicine in London, stated that the concept of the myopathies is as yet not firmly established and that the characteristics of the various groups are not clearly delineated, nor their dividing lines sharply drawn.

Neuropath vol 10 p 107

In an editorial³ discussion of Bramwell's⁴ Bradshaw lecture on the muscular dystrophies in the *Lancet* in 1925, it was pointed out that one is not likely to reach any rational conception of treatment of the myopathies from clinical studies alone, and that chemical investigation in these conditions is an uncultivated field which will repay any labor that is spent on it. This statement

Chart 1—Excretion of creatinine and creatin- in normal persons
The asterisks indicate as noted in the legend on the left hand side the
number of cases in which creatine was not determined

is not quoted to minimize the important clinical contributions of the earlier investigators but rather to indicate along what lines further progress probably lies

It was shown by Folin⁵ in 1905 and a little later by Kliercker⁶ that the normal adult excretes from day to day uniform amounts of creatinine in the urine but no creatine or only very small amounts, especially in the case of the female. It was also shown that these findings are not readily altered in the normal person by the level of the protein in the diet. It has been claimed that the amount of creatinine excreted bears some relation to muscular mass but not to the tone or activity of the muscles. The significance of this relationship is as yet not entirely clear. Although some believe that it is related to the amount of creatine or creatine phosphoric acid stored in the muscles, the origin of creatinine from this source is by no means established, nor is the mechanism of its formation known.⁷ There appears to be, however, an intimate relation to carbohydrate metabolism (Mendel and Rose⁸ and Brentano⁹).

The relative amount of creatine in the urine is materially increased during childhood up to between 10 and 15 years of age and also in the adult during certain physiologic processes such as lactation or in a variety of pathologic processes such as fever, starvation, severe diabetes or other conditions associated with deprivation of carbohydrates, severe exophthalmic goiter and certain myopathies.

It was known as early as 1870 (Rosenthal¹⁰) that certain myopathies were associated with a disturbance

in creatinine excretion as indicated by a diminished daily output. This observation was confirmed by various investigators (Langer¹¹), and particularly by Spriggs¹² using the improved method for creatinine determination (Folin).

Levene and Kristeller,¹³ in 1909 carried out quantitative studies on the urine of patients with various muscular disturbances and found that in cases of progressive muscular dystrophy there was not only a low

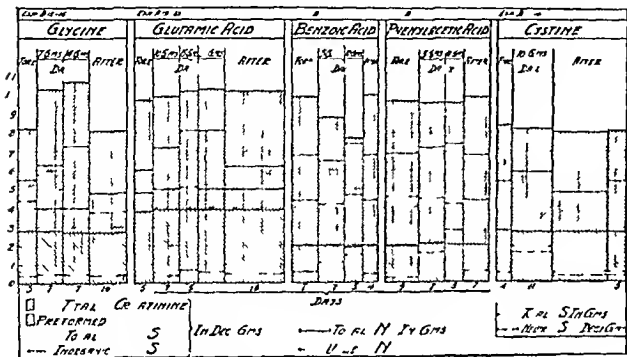

Chart 2—Average daily urinary excretion in muscular dystrophy

creatinine but also a high creatine output. They further observed that increased amounts of protein in the diet increased the amount of creatine excreted by such patients. And unlike normal adults these persons also eliminated a large percentage of small amounts of creatine administered orally. (Such diminished tolerance to creatine is present in other types of creatinuria, and

when present may be influenced by the level of the protein intake.)

Gibson and Martin¹⁴ tried to determine what constituent of the protein molecule produced the rise in creatine excretion in muscular dystrophy but without any success.

In 1929 Brand, Harris, Sandberg and Ringer¹⁵ reported that when glycine, the simplest α -amino acid, is fed, in addition to the diet, to patients with progressive muscular dystrophy an appreciable increase in the creatine excretion takes place. It was also found that arginine, cystine, glutamic acid, histidine, nucleic acid and various other compounds¹⁶ produced no such

effect.¹⁷ (Guanido acetic acid, however, was found to produce a marked rise in creatine excretion, as had been previously observed.)

A list of the various compounds which have been studied is given in the accompanying table.

It is well known that the administration of benzoic acid results in a loss of glycine from the body owing to the excretion of a combination of the benzoic acid with glycine in the form of hippuric acid. This fact was utilized to determine the effect of such losses of glycine on the creatine excretion in cases of muscular dystrophy. It was repeatedly found that the administration of benzoic acid produced a prompt and appreciable decrease in the creatinuria.

Since, as already stated, the feeding of glutamic acid produced no effect on the creatinuria, it was considered desirable to investigate what effect the withdrawal of glutamic acid would have on the creatine excretion. This was accomplished by feeding phenylacetic acid, which in man is known to be excreted in combination with glutamine as phenyl-acetyl glutamine. It was found that such feeding had no effect on the level of creatine excretion.¹⁸

Some of the experiments referred to are summarized in charts 2 and 3.

The various experiments which we carried out all indicated that there is a special and significant relationship of glycine to creatine metabolism.¹⁹

Thomas, Milhorat and Techner,²⁰ who were the first to repeat some of our experiments, were able to confirm our observation regarding the effects of glycine and of glutamic acid on creatine excretion. Because of the importance of creatine in the physiology of muscle, these authors fed glycine over prolonged periods of time to various patients with involvement of the muscular and neuromuscular system, and reported that the prolonged administration of this amino-acid had a marked therapeutic effect in some cases of pro-

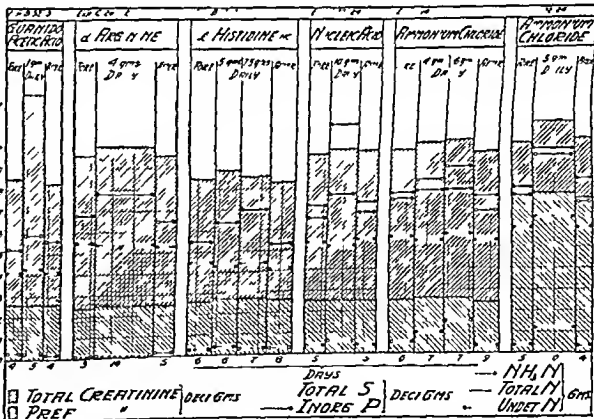

Chart 3—Average daily urinary excretion in muscular dystrophy

gressive muscular dystrophy. A number of other investigators²¹ have also reported favorable therapeutic results.

Reimen²² and Boothby²³ more recently have reported that glycine and glycine plus ephedrine produced marked improvement in cases of myasthenia gravis

In 1932 we resumed our metabolic studies in the myopathies especially to determine the therapeutic effects of the prolonged administration of glycine²⁴

Twenty-four hour specimens of urine were collected daily from all the patients studied in the hospital and from some of the outpatients. In the latter group whenever continued daily collections were not feasible from two to four twenty-four hour samples of urine were obtained weekly. All the samples were analyzed for total nitrogen creatinine²⁵ and creatine. The urine from the patients with dystrophy studied in the hospital was also examined for total sulphur or inorganic sulphur and inorganic phosphorus. In special experiments the nitrogen and sulphur partition was determined in addition.

As soon as the urinary data indicated that the patients had become stabilized metabolically a creatine tolerance test was carried out by giving the patient creatine in 0.5 Gm doses or multiples thereof for varying periods, as indicated in charts 4 and 5, and determining what percentage of the creatine fed was eliminated. The patient was then placed on glycine in doses of from 7.5 to 25 Gm daily for varying periods, as indicated in charts 4 and 5.

Cinematographic records were made in order to obtain some objective record of the disabilities of the patients. In some of the cases determinations of chronaxia and other electrical tests were carried out. The patients were examined from time to time to determine any subjective or objective signs of improvement.

METABOLIC OBSERVATIONS

1 *Creatinine Excretion*—In patients with progressive muscular dystrophy who were comparable in regard to age sex and weight it was found that the amount of creatinine excreted daily was lower the greater the incapacity of the patient. In fact in some of the older patients who were badly incapacitated (as indicated by 1 in chart 4) the creatinine excretion was as low as or even lower than the creatinine

Chart 4—Excretion in progressive muscular dystrophy

We shall report in this paper the studies in a group of cases of progressive muscular dystrophy and also in another group of various types of neuromuscular involvement. Although a large number of cases were investigated we have included in these two groups only those which were studied more intensively from both the metabolic and therapeutic standpoint.

In chart 4 some of the observations on twenty cases of progressive muscular dystrophy are summarized. The patients ranged in age from 7 to 47 years and included only one female. They presented varying degrees and types of muscular involvement. Patients 13 and 17 were brothers, and patients 2, 8, 11 and 20 gave a familial history of the disease.

In chart 5 some of the observations on thirteen patients forming a heterogeneous group of neuromuscular conditions are summarized.

PROCEDURE AND METHODS²⁶

The patients may be divided into two groups: those studied in the hospital (cases 1, 7, 11, 13, 14, 15, 16, 17, 18, 19, 1a, 3a, 5a, 6a, 7a and 8a) and those studied in the outpatient department. The patients in the hospital were put on weighed meat-free diets such as were used in our earlier studies¹⁵. For the purpose of the various tests to be subsequently described the protein level was kept at approximately 60 Gm and later increased in some patients to about 100 Gm. The outpatients were also placed on meat-free diets and although the food was not weighed in these cases the protein level was approximately the same, judging from the nitrogen excretion in the urine. After the necessary metabolic observations these patients were permitted to return to their meat diet except for intervals of a few days when special metabolic observations were made.

Chart 5—Excretion in various neuromuscular conditions

excretion of some of the children who were not so badly incapacitated (compare cases 12, 13, 17, 18 and 19 with case 8). The creatinine coefficients²⁸ in this group range between 10 and 22 which is lower than the values reported in the literature for infants 5 months of age (chart 1).

27 In the later part of this study the Folin creatinine and creatine determinations were carried out with the Pulfrich photometer (Ka. J. Biol. Chem. 100 1933).

28 $\frac{\text{mg creatinine nitrogen in 24 hours}}{\text{kg body weight}} = \text{creatinine coefficient}$

24 Brand E and Harris M M. J Biol Chem 100 22 1933
25 Although several neurologists express the opinion that this female patient (case 16) presented dystrophic manifestations they were not entirely certain as to the clinical diagnosis.
26 Dr E C Zabrickie and Dr C C Hare of the Neurological Institute of New York furnished valuable opinions regarding the neurologic status of the cases. Some clinical observations in a special group of the cases will be reported jointly in a separate communication. Dr H S Millet made a number of chronaxia determinations.

The level of creatinine excretion remained constant²⁹ from day to day over prolonged periods. Two of the cases recently studied for the therapeutic effect of glycine had been under our observation five years previously at Montefiore Hospital. The creatinine excretion determined under the same dietary regimen was slightly diminished after this long interval, showing the rather remarkable constancy of the creatinine excretion in these conditions. This slight drop in creatinine excretion was accompanied by a slight increase in incapacity over a period of several years (chart 6).

In some instances the creatinine excretion rose slightly as a result of a marked increase in the protein intake (especially in the form of casein) in addition to glycine feeding. This was not accompanied, however, by any apparent improvement either subjectively or objectively in the incapacity of the patient.

The creatinine excretion in the cases of muscular dystrophy was unaltered by the creatine administered for the tolerance test.

As can be readily seen from charts 4 and 5, the creatinine excretion in the various neuromuscular conditions was much greater than that found in comparable cases of muscular dystrophy.

Chart 6—Changes in average daily urinary excretion in cases 13 and 17 over a period of years.

2 Creatine Excretion—It is well known that creatinuria is dependent in part on the level of the nitrogen in the diet. However, if one compares patients at the same level of protein intake it will be found that those with muscular dystrophy will usually excrete larger amounts of creatine than comparable patients suffering from neuromuscular conditions. It is surprising that although the creatinine excretion is low in muscular dystrophy, the excretion of total creatine bodies in this group is within the range of that found in normal persons, children as well as adults. In other words, the relative amount of creatine is increased in these cases.

The muscular dystrophy group showed a markedly diminished tolerance for creatine (chart 4). From 40 to 120 per cent of the creatine fed was promptly eliminated. In a general way the diminished tolerance bore some relation to the severity of the clinical manifestations and also to the level of creatinine excretion. Of course this relationship is not an absolute one since the creatine tolerance is somewhat influenced by the level of protein intake.³⁰

²⁹ In case 16 with a questionable diagnosis of muscular dystrophy the creatinine rose from a daily average of 0.71 Gm to 0.79 Gm after four months of glycine therapy. The patient gained 11 pounds (4.9 kg) during this period but otherwise her condition remained essentially unchanged.

³⁰ The tolerance test in case 14 was carried out when the patient was on a high protein diet and excreting about 13 Gm of nitrogen per day. This probably influenced in part the high percentage of excretion obtained.

In the neuromuscular conditions, as can be seen in chart 5, the creatine tolerance was, generally, considerably greater than that found in the muscular dystrophies. In five of the eleven cases in which the creatine tolerance was tested, little or none of the administered creatine was eliminated. In several cases, especially those diagnosed as the Charcot-Moore type of muscular atrophy, the creatine tolerance was somewhat diminished. In the latter group, however, patient 2a was a girl and patient 4a had dystrophic manifestations. In cases 1a and 4a the administration of creatine tended to increase slightly the creatinine excretion.

3 Effects of Glycine Administration—The daily administration of glycine in varying amounts (from 2.5 Gm daily) and for variable periods of time indicated in charts 4 and 5, produced no effect on creatinine excretion in the cases of muscular dystrophy with the exception of case 16.³¹ In the neuromuscular group only slight increases were observed in a few cases. The creatine excretion, however, was appreciably increased in the cases of muscular dystrophy even with the oral administration of 7.5 Gm of glycine daily, with the exception again of cases 16 and 4. In three of the cases, indicated by a question mark in chart 4, metabolic conditions were unsatisfactory, determining this effect.)

In the neuromuscular conditions 7.5 Gm of glycine daily produced no effect on the creatine excretion even in those cases falling into the group of Charcot-Moore type muscular dystrophy, which were also peculiar as previously indicated, in regard to their creatine tolerance. Larger doses of glycine, however, produced a rise in creatine excretion in some of the patients with neuromuscular conditions, which rise, when it occurred, was usually less than that seen in the cases of dystrophy (compare chart 5 with chart 4).

Our observations in regard to the effect of glycine on creatine excretion in muscular dystrophy were essentially the same as those which we had observed in earlier studies in 1927 to 1929, which were reported at the Thirteenth International Physiological Congress in Boston.¹² However, we did not observe the sparing effect on nitrogen and sulphur metabolism, which we had noted to follow glycine administration in our earlier studies. The details of these experiments will be reported elsewhere.

The rise in creatine excretion which we observed with glycine was the result of superimposing varying amounts of it on a basal diet. The nature of this diet and its nitrogen level may influence in part the effect observed and is a subject which is under investigation at present.

Thus far we have not observed any drop in creatine excretion associated with a rise in creatinine such as Thomas and Milhorat³² reported for some of the cases, which they claimed was associated with clinical improvement following glycine therapy.

CLINICAL AND THERAPEUTIC OBSERVATIONS

Thomas and Milhorat³² reported that some of the patients developed peculiar itching and paresthesia of the muscles as a result of glycine therapy, which they stated usually preceded the clinical improvement in these cases. Up to the present we have observed this phenomenon in only a few cases of muscular dystrophy (cases 3, 5 and perhaps 8). Patient 20, who had been

receiving glycine therapy for several months and who did not experience this phenomenon, subsequently was given glycine and ephedrine, following which paresthesia developed in the muscles

None of our patients with muscular dystrophy receiving glycine therapy³¹ have as yet shown any striking improvement such as that reported by Thomas, Milhorat and Techner^{20a} and Kostakow and Slauck²¹

Of course, it would be difficult to ascertain whether any slight improvement had occurred which could not be readily detected owing to the lack of satisfactory methods for measuring such improvement. In two of the cases manifesting paresthesias (3 and 5) the families were of the opinion that the children were more active as a result of the therapy. However, objectively no notable change has been observed as yet. These patients are still under treatment. A number of patients, particularly patients 14 and 16, improved markedly in their nutritional state during the period of treatment with glycine, their disabilities, however, appear to have remained practically unchanged. Only one patient (case 11) with fairly well advanced muscular dystrophy became worse during the period of glycine administration. Thus aggravation in the clinical state of the patient was not associated with any changes in the creatine and creatinine excretion. As far as one can tell, the disease has not progressed in the other cases of muscular dystrophy during the period of observation and treatment. Because of the rather slow progress of the disease it is too early to say whether prolonged glycine administration will affect the future progress of the disease in these cases.

In practically all of our cases of muscular dystrophy we have observed loss of the sternal portion of the pectoral muscles with preservation of the clavicular portion except in three far advanced cases (12, 13, 17) in which even the clavicular portion was lost. According to Bramwell⁴ this involvement of the sternal part of the pectoralis muscle is well known to most clinicians, and Gowers³² considered this observation as important as the hypertrophy of the calf muscles for the diagnosis of muscular dystrophy. One of our patients (9a) with marked involvement of the muscles of the shoulder girdle, who was sent to us as a case of muscular dystrophy, had metabolic readings which made us question the diagnosis. It is interesting to note that in this case the pectoral muscles were well preserved.

In the group of neuromuscular conditions charted no striking therapeutic effects from glycine have been observed. Patient 9a, after receiving glycine for ten weeks, stated that although his muscular power did not improve he felt that he did not tire as readily or feel as fatigued after a day's work as before the treatment. The patients with myasthenia gravis have received glycine for only a relatively short period of time and have not shown any notable improvement from this therapy.

COMMENT

Erb³³ in 1883-1884 did much to help clarify the clinical concepts regarding the myopathies and pointed out the probability that the various types described by Meyron, Duchenne Landouzy and Dejerine and by

himself were variants of the same disease and suggested the use of the term progressive muscular dystrophy for the primary myopathies. However, controversy³⁴ still prevails regarding the pathologic observations in this group of diseases and the relationship between the various clinical entities which have been described.

A number of investigators (Meyenburg^{34b}) have reported the absence of any demonstrable changes in the nervous system of patients with progressive muscular dystrophy. This, as Bramwell⁴ pointed out, is a negative conception, and one cannot be certain that functional alterations in the nervous system do not exist which are not demonstrable histologically. In fact, Erb³³ himself, among others, was rather inclined to the view that a trophoneurosis could not be ruled out, and furthermore he pointed out that these patients or members of their family not infrequently had other evidence of involvement of the nervous system, such as idiocy, mental deficiency, epilepsy, chorea and various psychoses.

Another group of investigators^{34b} have reported changes in the anterior and lateral horn cells of the

Chart 7—Chemical formulas of creatine creatinine glycine and arginine

spinal cord consisting of either atrophy or diminution in the number of cells, this being especially noticeable in the lateral group of cells. However, as Holmes³⁵ who reported such a case, stated, it is difficult to determine whether the observed alterations in the spinal cord are primary or secondary to the changes in the muscles or whether they are the result of the same etiologic factor producing the muscular dystrophy.

The problem is further complicated if one considers the possible relation of amyotonia congenita, myotonia atrophica or dystrophica etc., to this group of diseases. Furthermore, Meyenburg^{34b}, Holmes³⁵, Spiller³⁶ and others pointed out that it is not always easy to differentiate the primary myopathies from other diseases of the neuromuscular system. This has led, according to Meyenburg^{34b} to the grouping of various progressive muscular atrophies into one large group and the discarding of dividing lines. Opinions are divided, however as to the advisability of such a procedure.

31 The effect of glycine on so-called nutritional muscular dystrophy (Coetesch M and Pappenheimer A M J Exper Med 54 145 1931; McCay C M, Madson L I and Maynard L A J Biol Chem 100 191 1933) in guinea pigs and rabbits was studied. No therapeutic effect was observed.

36 Spiller W G Tr Internat Cong Med London 1913 Neuro-path vol 10 p 115.

In this unsettled state of knowledge it is possible that the variable therapeutic results which have been obtained with glycine may be due to the difficulty in recognizing clinical entities which are as yet not sufficiently differentiated.³⁷ In this connection careful metabolic observations correlated with pathologic data should help considerably in clarifying the picture.

In regard to therapeutic measures it may be of interest to state that a number of earlier investigators, owing to the absence of involvement of the nervous system have considered the muscular dystrophies as due to a nutritional disturbance. On this basis Parhon and Savini³⁷ fed two children with muscular dystrophy fetal muscles with the idea of supplying essentials which might be lacking for normal muscular development. They reported improvement in the two cases following this treatment. This form of nutritional therapy has apparently not been further investigated.

Whether the endocrine glands play a role in this condition, as has been suggested by Janney, Goodhart, Isaacson³⁸ and others is still a disputed point and worthy of further consideration especially as knowledge of the endocrines rapidly increases and more effective therapeutic products become available.

The claims that the muscular dystrophies are due to pathologic changes in the sympathetic system and the therapeutic use of epinephrine and pilocarpine as recommended by Stecherbak,³⁹ Ken Kure⁴⁰ and some of their followers require further study from the standpoint of the pathologic processes and the therapy indicated.

Space does not permit any detailed discussion of the complicated aspects of the metabolism of creatine and creatinine and the significance of these substances for various phases of normal and pathologic physiology. Furthermore the information at present available, although extensive, is as yet insufficient to give us an insight into the disturbances of creatine and creatinine metabolism observed in the myopathies. Elucidation of this problem should yield important information regarding the nature of the pathologic physiology in this group of diseases. Even in the light of present knowledge, however, investigation of creatine and creatinine metabolism in the myopathies as indicated in this paper, will be found of aid in diagnosis of value in the study of the progress of the disease and perhaps of assistance in following the response to therapeutic measures.

SUMMARY

1 Metabolic and therapeutic studies have been carried out in a group of muscular and neuromuscular conditions.

2 The effect on creatine metabolism of the feeding of glycine and the other amino-acids which go to form glutathione was reported. These results were further substantiated by experiments in which glycine and glutamine were withdrawn from the metabolic mixture by the feeding of benzoic acid and phenylacetic acid respectively. The effect of a number of other substances was indicated.

3 The value of the study of the metabolic effects of creatine and glycine administration as an aid to diag-

nosis in muscular and neuromuscular diseases was pointed out.

4 The therapeutic effects of prolonged glycine administration were reported and other lines of investigation indicated.

ABSTRACT OF DISCUSSION

DR EDWIN G. ZABRISKIE, New York. The authors have presented a pathway that may lead eventually to more accurate diagnostic methods and help to clarify the confusing picture of myopathies. In one group of six cases in which certain strikingly similar clinical features prevailed the therapeutic results were negative. This group is the subject of careful investigation at the present time and I will do no more than mention certain striking characteristics, namely, an extremely wide angle of the jaw, so wide that the occlusion of the incisors fails in some instances by an inch and a half. They nearly all have extremely thick, fleshy tongues and the usual early contractures chiefly of the flexors of the achilles tendon of the biceps femoris, the biceps of the humerus, and also a peculiar and rather unique hypertrophy of the anterior peroneal group accompanied by almost complete loss of voluntary motion with loss of mechanical irritability as well as of reflexes. This particular group gave no evidence of improvement at all with glycine. In others some subjective improvement was reported. It corresponded to that reported by Thomas and others, namely, paresthesias of the muscles but it was very slight.

DR HANS H. REESE, Madison, Wis. Drs. Harris and Brand should be given full credit for having instituted at least the studies on myopathies in regard to the creatine and creatinine metabolism. At the Wisconsin Psychiatric Institute at Madison we have treated six cases of progressive muscular dystrophies. The reason that work is progressing so slowly is the tremendous cost of glycine. When we started we had to pay \$120 a pound and the patient should have at least 10 Gm a day. Of late the price has come down but we have felt that our results are much better with another amino acid, and we have used glutamic acid. With glutamic acid one gets more muscular stimulation and perhaps a quicker response than with glycine. This is especially manifest in small children. With glutamic acid definite muscular paresthesias present themselves at the beginning of the treatment. I am ready to state that we have not cured any of these muscular dystrophies although the patients have improved in their locomotion and activities. Subjectively they feel stronger and less tired.

DR MEYER M. HARRIS, New York. I wish to thank Dr. Zabriskie for the interest he has shown in this study and for his close cooperation. The cost of glycine is much less than it has been. Some manufacturers are putting out glycine at about \$11 a kilogram or \$5 a pound. The early prohibitive cost is becoming less of a factor in treatment than it was in the early part of the studies. We used glutamic acid as one of the controls, and we gave as much as 20 Gm of glutamic acid a day for a prolonged period. We did not observe any of the paresthesias or any striking effects following its administration in these particular cases. We are at present studying the effects of combinations of the amino acids and as a part of this work we are planning to undertake other investigations with a substance called glutathione. It is a rather expensive compound which contains in its molecule glutamic acid, glycine and cysteine. It is a compound that is very important in oxidation and reduction mechanisms and probably also in detoxifying mechanisms in the body. We keep at present some patients on various combinations of amino acids and others on various combinations of amino acids and proteins such as casein, which according to Bollman has some peculiar effect on the creatinine excretion. The effective amino acids influence only the creatine but not the creatinine excretion. Creatinine is supposed to bear some relationship to muscular mass and the health of the muscles in an individual. Thomas has reported in his one or two cases in which improvement took place that this was associated with a rise in the creatinine excretion. This is a result one would hope to obtain since it would indicate improvement metabolically.

TOXICITY OF ALPHA-DINITROPHENOL

REPORT OF CASE

HAMILTON H ANDERSON, M D

ALFRED C REED, M D

AND

GEORGE A EMERSON, M S

SAN FRANCISCO

Prof C Heymans of Ghent has recently revived interest in the fever producing properties of nitrated naphthols,¹ a demonstration of which stimulated Tainter and his colleagues to study alpha-dinitrophenol. Others had shown also that the latter drug causes an increase in cellular oxidation.² Because of its metabolic stimulating qualities, this agent was proposed and used by Cutting, Mehrtens and Tainter³ for the clinical treatment of obesity, hypothyroidism and similar depressed metabolic states. They especially warned against its toxicity, stating that "there are limitations to and possible dangers from the use of the drug clinically. It should be used only under strictly controlled conditions." Since hearing this report we have had a case of intolerance to alpha-dinitrophenol which prompted us to inquire into the toxicity of the compound in an effort to determine contraindications to its use and methods for detecting untoward effects.

Perkins, in a comprehensive review (especially of Mayer's early inaccessible work)⁴ reported a marked variation in the susceptibility of munitions workers exposed to dinitrophenol during the World War. Alcoholic addicts and men with renal or hepatic disease, tuberculosis, malaria or chronic rheumatism have a lessened resistance to the agent. In subacute intoxication "workers claim that they have grown thin to a notable extent after several months' work in DNP. Many complain of general weakness with headaches and dizziness with moderate sweats especially at night." Acute toxicity may come on suddenly, death occurring within a few hours when large amounts are taken into the body, according to Perkins. Alice Hamilton⁵ has suggested means of preventing dinitrophenol poisoning and the Council on Pharmacy and Chemistry of the American Medical Association⁶ has commented on the numerous cases of toxicity that occurred in France during the World War.

Examination of the tissues of human beings dying of dinitrophenol poisoning reveals no characteristic lesions. Edema of the lungs and fatty infiltration of the liver may occur according to Mayer⁴ who made

the first extensive toxicologic study of the agent in 1915. Blood, urine and certain viscera contain sufficient amounts of the drug to give a positive Derrien test.⁷ This may be used to determine the presence of the drug in the urine of patients under treatment, and if the agent persists daily or increases in amount it is to be considered a sign of intolerance, according to Perkins.

In the clinical trial of alpha-dinitrophenol in fourteen cases of obesity, treated as recommended by Cutting, Mehrtens and Tainter, we encountered one severe toxic reaction which differed from case reports found in the literature.

REPORT OF CASE

History—D A L, a woman aged 43, white, married, a housewife, complained of overweight, an increase in the past year of 45 Kg. her present weight is 79.5 Kg, her height is 171.4 cm.

At midnight of the day following fourteen days of alpha-dinitrophenol therapy (0.075 Gm of sodium 2,4-dinitrophenoxide three times a day by mouth) the patient complained of severe pruritus confined to both elbows, a small area in the center of her back, the cervical region just below her ears and over both knees. At 6 a.m. the following morning a maculopapular erythematous eruption appeared in the regions noted with a slight swelling of the soft tissues. She was given a powder containing calcium gluconate 1 Gm and ephedrine sulphate 0.025 Gm orally four times a day for four days. Calamine lotion was applied to the affected areas. During the day the pruritus eruption and edema became more severe and extensive. Lassar's paste without acid was applied locally and codeine phosphate in 0.033 Gm doses was given by mouth to relieve her. Twenty-four hours after the onset the whole body, excepting her face and scalp, was involved, with edema of both arms, the left shoulder, the neck and the lobes of both ears and erythematous lesions were found on the back, chest and abdomen and all four extremities, especially over the joints. There was no nausea, diarrhea, dyspnea, dysphagia, dysuria, frequency or discolored urine. The skin manifestations were most acute from forty-eight to seventy-two hours after onset when in addition to the pruritus, pains developed on motion of the fingers and all large joints. The patient complained also of pains in the palms of her hands and in the soles of her feet. Amidopyrine in 0.33 Gm doses was added to the codeine for relief. A nurse was in constant attendance during the five days the patient was confined to bed. On the fourth and fifth days the skin lesions, edema, pruritus and pains subsided and on the sixth and seventh days the only symptoms complained of were stiffness on motion of all large joints. Swelling persisted in the left wrist and fingers which were tender on motion and paresthesias of the fingers of the right hand were present. The skin was entirely clear except for scaling at the sites of the lesions. Since then the patient has had severe pains in one or more joints, without swelling of the soft tissue but rest, amidopyrine and heat afford prompt relief. The temperature, pulse and respiration rate were normal throughout. The patient lost 15 Kg during the two weeks of therapy and after discontinuing alpha-dinitrophenol she lost 25 Kg during the third week.

The family and the marital history were not significant.

The patient lived in California all her life and has been well except for pyorrhea and a chronic hypertrophic arthritis of the cervical spine and both knees. Two years before examination she had a mild dermatitis venenata of the face and neck and just before this had influenza. She gave no personal or family history of allergy or venereal disease. She had not been exposed to

7 Derrien's test: To 10 cc of urine add 1 cc of 10 per cent sulphuric acid and then 1 cc of 0.5 per cent sodium nitrate. Shake and keep in the dark for five minutes. In another tube (about 25 cc capacity) place 2 cc of a freshly prepared 0.5 per cent betanaphthol solution in ammonia water (22B). Pour treated urine into the betanaphthol tube and allow to stand a minute or longer and add 10 cc of sulphuric ether. Shake well and cork tube and flow ethereal solution to separate. Interpretation: If the color of the ether is violet, wine color or orange red the reaction is positive, indicating the presence of dinitrophenol and products; if colorless or yellow the reaction is negative.

poison oak for at least a week preceding her present illness. Her habits were regular. She had taken no other medication immediately before this illness. Physical examination revealed nothing except as noted. The blood pressure was 120 systolic, 70 diastolic.

Examination.—Examination of the urine was negative on several occasions during the five years she has been under observation, and specimens examined after alpha-dinitrophenol therapy were normal also. Derrien's test was negative. Examination of the blood showed hemoglobin 83 per cent before and 74 per cent (Sahli) after therapy, red blood cells, 4,850,000 before and 4,300,000 after, white cells 11,900 before, with 73 per cent neutrophils, 24 per cent lymphocytes, 3 per cent monocytes, and after treatment, 14,200 white cells with 69 per cent neutrophils, 25 per cent lymphocytes, 3 per cent monocytes, and 3 per cent eosinophils. The basal metabolism was 7 per cent plus, fasting blood sugar 100 mg per hundred cubic centimeters, icterus index 39, van den Bergh reaction was negative, non-protein nitrogen was 34.5 mg per hundred cubic centimeters and creatinine 1.3 mg per hundred cubic centimeters after alpha-dinitrophenol therapy. Roentgenograms of the left wrist and left knee revealed no demonstrable bony pathologic changes⁸ after treatment.

The thirteen other cases treated with comparable amounts (about 3 mg daily per kilogram) of the drug for periods up to two months did not suffer any appreciable ill effects. The average weight loss for the first month of therapy was 2.3 Kg, and for the second month the loss averaged 2.1 Kg. The diet was limited to foods low in sugar and fat.

EXPERIMENTAL TOXICITY STUDIES

As a result of this single severe toxic reaction, we made a quantitative study of the toxicity of the sample of alpha-dinitrophenol used in this series of cases. The melting point of the sodium 2,4-dinitrophenoxide⁹ used was determined to be 297 C, agreeing with samples of the drug used by Tainter¹⁰ and known to be chemically pure. Mayer⁴ contends, however, that impurities are not responsible for the untoward effects noted. He further states that there is a variable susceptibility to

Chart 1—Temperature curves with alpha dinitrophenol (ten rats per group)

the poison in the same species of animals. In the horse, dog, rabbit, pigeon, turtle and frog the toxic dose is 10 mg per kilogram. The agent is toxic regardless of the method of administration. He reports Dinitrophenol is termed a specific poison causing exaggeration of heat radiation and vasodilatation, with a progressive rise of temperature to 45 C (113 F) and

death. It causes a general stimulation of cellular oxidation. Koelsch,¹¹ in 1927, reports tolerance to the agent when swallowed in doses of from 20 to 30 mg per kilogram but observed death with amounts of 50 mg per kilogram. He terms dinitrophenol a specific protoplasmic poison which may cause renal damage and fatty degeneration of the liver. Magne, Mayer and Plantefol¹² confirmed Mayer's original observations on toxicity, i. e., doses of from 10 to 50 mg per kilogram are fatal to dogs, and pigeons, rabbits and frogs are also susceptible. Cutting and Tainter¹ found

Chart 2—Toxicity of alpha dinitrophenol intraperitoneally in rats (ten animals at each dose)

that from 5 to 40 mg per kilogram produced fever in various animals and man and state that the "margin between the febrile and the fatal dose is narrow."

In our experiments in rats we limited ourselves to determinations of the lethal range of the agent and the character of the temperature rise and finally attempted to determine whether edema occurred in animals given the drug. Ninety fasting normal rats were kept under identical conditions of temperature and humidity and were each given a single dose of the drug intraperitoneally in amounts ranging from 10 to 50 mg per kilogram. Temperatures were taken rectally at thirty minute intervals over a five hour period. The results are noted in chart 1. Ten normal control animals injected intraperitoneally with a corresponding amount of physiologic solution of sodium chloride were kept under identical conditions without showing an appreciable alteration in temperature. Chart 2 reveals the lethal range for the agent in the group of rats studied. Fifty per cent of the animals died with 40 mg per kilogram and all rats given 50 mg per kilogram died immediately after the height of pyrexia, which occurred within the first hour. No gross evidence of edema or other tissue damage was observed in any animal.

COMMENT

A case of alpha-dinitrophenol allergy (total oral dose of 39.3 mg per kilogram over fourteen days) is presented, which may be termed a "qualitative idiosyncrasy," according to Storm van Leeuwen's classification.¹² It is apparently not an instance of small therapeutic amounts of the drug producing symptoms described for the known toxic effects of large doses. Dr. Tainter has told us of cases of cutaneous reactions to the compound somewhat similar but less severe than the one described here. Unfortunately, we were not

familiar with Perkins' warning that individuals with chronic rheumatism, alcoholism, tuberculosis and renal and hepatic disease have a lessened resistance to the agent. Our patient suffered from chronic hypertrophic arthritis before therapy, and after alpha-dinitrophenol had severe intermittent joint pains in areas previously not involved. There was no evidence, however, of permanent organic damage so far as physical examination and laboratory tests could determine. The thirteen other patients given the drug in therapeutic amounts had no apparent untoward effects. It is suggested that Derrien's test be used in determining the presence of the agent in the urine of patients under treatment as a means of detecting intolerance to the drug, although in this case of allergy the test was of no value.

The toxicity in rats of the compound used in this group of patients corresponds to the reports of previous investigators, the average lethal dose being 40 mg per kilogram. Toxicity work of this character, however, is of no value in predicting the occurrence of allergic responses. It is especially to be noted that the toxic range of alpha-dinitrophenol is broad, indicating a high probability of untoward reactions at relatively low dosage. On this account, dosage in human beings must be strictly and conservatively controlled, and it is recommended that it be based on average body weight for age, sex and height of the patient. In our opinion, it is yet to be demonstrated that this drug is as safe and satisfactory for weight reduction in human beings as other methods in common use.

COMMENTS ON THE HIGHER X-RAY VOLTAGES

ALBERT SOILAND, MD, DMRE
LOS ANGELES

The headline publicity which has been broadcast over the nation calling attention to this or that 1,000,000 volt x-ray machine as a cancer cure is both ill timed and unfortunate. In the first place, there are in the United States today only two higher voltage institutions (one in California and one in New York) which have successfully maintained a therapeutic voltage over 500,000 for an appreciable time period. In the second place, neither of these institutions, to my knowledge, is willing to claim any extraordinary results or reactions over those formerly achieved. Several years must elapse before an authentic evaluation can be placed on any clinical reactions from this new x-ray colossus which would warrant the assumption that cancer is thereby brought any nearer to solution.

From a survey of the results of efforts in developing the higher x-ray voltages up to the present, one may accept as a fact that the shortest effective wavelength now available corresponds to a voltage of between 500,000 and 600,000. At these potentials a tube carrying 5 milliamperes emits a radiation intensity that is comparable to that from approximately 500 Gm of radium. With such an enormous amount of radium, a great many more hard gamma rays would be found than in the x-ray tube mentioned while a greater proportion of radium gamma radiation would be inactive

in that it would not be absorbed but would penetrate through and beyond the tissues within the usual therapeutic range.

From an economic standpoint, therefore, the comparison is very largely in favor of the x-rays, as the cost of 500 Gm of radium would be insurmountable, so that it will never be known what a radium content of that immensity might offer. On the other hand, the expense connected with an x-ray equipment to yield the

Fig 1—Control room of 600 kilovolt x ray tube, Soiland Clinic.

equivalent radiation energy is well within the cost range of certain standard hospital and clinical groups.

Experimental work on the higher voltages has been made possible through the courtesy of Dr Robert A. Millikan of the California Institute of Technology and his associate, Dr Charles C. Lauritsen, who designed and built the first high voltage tube some five years ago.

An opinion cannot yet be vouchsafed as to the ultimate clinical value of the Lauritsen tube. It is known that from the ordinary 200 kilovolts (peak voltage) a depth dose of approximately 38 per cent is obtained at a depth of 10 cm of tissue, so that the deep effect is obtained only at a tremendous expense of energy wasted in the first part of the volume under treatment, that is, the superficial structures.

With approximately 500 kilovolts on the tube, however, practically a 45 per cent depth dose is obtained at the level of 10 cm from the surface, thus opening up a field to high voltage roentgen therapy not hitherto obtained.

It is not my intention in this communication to suggest that the new high voltage roentgen tube will supplant radium. But it is possible, when its distribution has become more generalized, that it may supplant the use of the very large and expensive radium pack or radium gun, affording opportunity to convert the latter into highly filtered platinum needles or tube applicators for interstitial use. This type of treatment offers an entirely distinct and different field from that of external radiation. It is my opinion that in the near future radium will be employed largely for interstitial applications, and short wave x-rays for treatment from the exterior.

If the high voltage x-ray tube under discussion does nothing more than replace the expensive radium pack, it will have well served its purpose. Coincidentally, the price of radium may perchance be reduced to a point at which it can be obtained at a more reasonable price and thus made available to institutions and radiologists who have heretofore been deprived of its use.

Patients from my clinic who have been submitted to the Lauritsen tube have, in some instances, shown interesting reactions. Some with extensive secondary carcinoma of the glands of the neck, primary in the

dose, and a 200 kilovolt tube with ordinary filtering can be raised from a 10 cm depth dose of 40 per cent to one of 48 per cent by changing from a 50 cm to a 100 cm skin target distance. Thus, although the proportion of the primary radiation which reaches this depth is very different in the two cases, unless intense γ -rays from the atomic nucleus are excited, no extreme gain in depth dose is to be expected by using very high voltage tubes. As to the biologic factors, no evidence is yet available for a very large intrinsic divergence between the effects of 200 kilovolt radiation and radium gamma rays, in other words, he concludes that it has not been demonstrated that biologic reactions will increase very greatly as the voltage is raised above 200 kilovolts. As Dr Tuve was the first man to work with extreme high voltage through a vacuum tube, his statements must be given respectful consideration.

Dr Failla of New York, physicist at the Memorial Hospital, has been operating a high voltage plant up to 750 kilowatts. From his rather guarded statements it would appear that no startling changes, either in clinical results or in biologic reactions, have been obtained. It seems however, that Dr Failla does believe there is a biologic change which increases in degree with the rise of the voltage.

From this it will be seen that Dr Tuve and Dr Failla hold somewhat opposite opinions on this point.

To Dr Lauritsen however, belongs the credit of being first in the field with a practical high voltage γ -ray tube, one of which to my knowledge, has functioned satisfactorily under a voltage of 1,200,000. It is this type of tube with which I am concerned in the

Fig 2--Arrangement of rooms

tongue, lip or tonsil which had already been appreciably reduced with the 200 kilovolt tube and had become radiation-fast were perceptibly benefited and in a few instances the use of the big tube caused entire disappearance of the growth. Similar reactions were observed in certain types of carcinoma of the fundus, metastatic carcinoma from the breast and (in one patient) carcinoma of the rectum. Not in all were preliminary responses equally satisfactory, but enough has been observed to warrant the belief that time and experience will bring better results than are now obtained with the 200 kilovolt apparatus.

Whether the apparent improvement in results secured with the new tube is due to a biologic difference between it and the old or whether it is due to a more homogeneous radiation permitted by heavier filtration, only time can tell. One virtue which must not be overlooked is that of lessened skin reaction. With the super-high voltage tube a greater proportion of the radiation energy penetrates to the deeper levels of the body, with a relatively decreased skin reaction.

A great deal of research work is necessary before any definite conclusions can be reached. We are still far from a solution, or even a reasonable working hypothesis for biologic reactions though many outstanding scientists are indefatigably working with these perplexing problems.

The Carnegie Institution of Washington, at its Department of Terrestrial Magnetism in Washington, has developed high voltage vacuum tube equipment operating at potentials up to 2,000 kilovolts. This apparatus is not designed for therapeutic use but for investigations of the atomic nucleus. In connection with this apparatus Dr Tuve of the department's staff has made some interesting calculations regarding the depth dose possibilities of high voltage tubes. From his curves the calculated 10 cm depth dose of a 2,000 kilovolt γ -ray tube filtered heavily by lead and with a 50 cm skin target distance, is 50 per cent of the skin

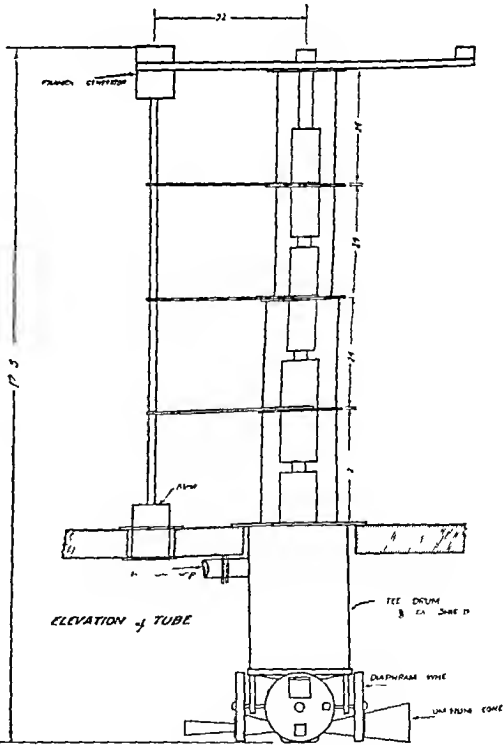

Fig 3--Elevation of tube

present discussion, an early edition of which has been in operation for over two years, with no serious breakdowns and with a total number of γ -ray hours unheard of in any tube that has ever been presented to the medical profession for therapeutic work. To Dr

Lauritsen, therefore, the medical world is indebted for the development of the world's first practical therapeutic x-ray unit of more than one-half million volts a recent duplicate of which I am now operating in my own clinic for therapeutic purposes

The achievement of one million volts is but a beginning, according to Dr Lauritsen, and it is quite possible both electrically and architecturally, to construct a transformer and tube of almost unlimited voltage. What this may mean to medical practice of the future staggers the imagination. If time should demonstrate that its usefulness increases in proportion to its rise in voltage, a new field of endeavor will open for those men who have faith in radiology and who continue to labor earnestly to keep pace with each progressive step, and will mean much to an expectant public, which demands from these members and workers of the medical profession that they give to them and to the afflicted the fruit of their labors.

That my clinical associates and I have been permitted to take part in the high voltage research work is sincerely appreciated, and we are grateful to the officers and research workers of the California Institute of Technology for this privilege.

OVARIAN TUMORS ASSOCIATED WITH SECONDARY SEX CHANGES

GRANULOSA CELL CARCINOMA AND
ARRHENOBLASTOMA

EMIL NOVAK, M.D.

AND

J. HERMAN LONG, M.D.
BALTIMORE

In the past few years a new chapter in gynecologic pathology with important clinical correlations has been written in the description of a group of ovarian tumors capable of producing profound effects on the sex characters of the individual. The credit for this new chapter belongs to the German school, and especially to Robert Meyer.¹ Our incentive for bringing this subject before this section is the fact that American pathologists have not yet manifested any great interest in this group of tumors, which while rare are almost certainly much more common than published reports would seem to indicate.

The older concept that tumor cells are purely parasitic and nonfunctional has been quite thoroughly disproved in at least a certain group of neoplasms more particularly those which arise in the endocrine structures. Illustrations will at once suggest themselves. I need mention only the obvious functional role of the cells of the acidophilic pituitary adenomas in the production of acromegaly or gigantism, the remarkable syndrome shown by Cushing² to be associated with certain basophilic adenomas of the same gland, the striking changes in the sex characters produced by some suprarenal cortical lesions, the somewhat similar

syndrome seen with some pineal tumors and so on. As regards some tumors at least, therefore, there seems ample justification for the dictum enunciated many years ago by Baird,³ that "the neoplastic cells continue to produce their physiologic secretions" ("les cellules neoplastiques continuent a produire leurs secretions physiologiques"). I need hardly add that an extension of this dictum to tumors in general is clearly not justified by available evidence.

The classification and nomenclature of ovarian tumors have always been a *bête noire* to both gynecologists and pathologists, chiefly because of ignorance of their histogenesis, although recent years have added considerably to knowledge on this point. For this reason a survey of the older material of any laboratory is apt to yield as many treasures as a hunt through an ancient attic. We have recently been thus reappraising the ovarian tumors in our own laboratory and, among other things, we have uncovered a number of tumors belonging to the category indicated by the title of this paper.

GRANULOSA CELL TUMORS

Without reviewing the evolution of knowledge of this interesting group of tumors, suffice it to say that the granulosa cell tumors are now commonly accepted as arising from the early oophorogenic structures in the sex gland area. The embryology of the ovary has not yet been unshakably established, although the evidence seems to point more and more to the correctness of the view, championed by Fischel,⁷ that the real germinal epithelium of the ovary is derived from the mesenchyme of the sex gland anlage. This is contrary to the hitherto rather generally accepted idea that the follicular apparatus is the result of downgrowth of the germinal epithelium covering the ovary into the mesenchyme beneath, in the form of medullary cords and later Pfueger's tubules. In either event there is further differentiation of the cells of the sex cords into two types, one becoming the oogonium, the other the follicular epithelium, the latter grouping themselves around the egg cells to form the primordial follicles.

In this process, rests of granulosa cells (*granulosaballen*) may be left over and indeed, these rests may at times be seen in postnatal ovaries. It is from these rests that the granulosa cell tumors arise and not, as some formerly believed, from the granulosa of adult follicles. As Meyer has emphasized, the epithelium of the adult follicle is a satellite tissue, depending for its life on the life of the ovum, to which it appears to be physiologically subservient. Furthermore, the fact that these tumors commonly develop late in life when the follicular structures have almost or completely disappeared from the ovary would speak against an origin from the granulosa of the adult follicle. Finally, granulosa cell rests sometimes of considerable size have been demonstrated their structure suggesting their probable importance in the origin of these tumors.

The granulosa cell is a typically feminine cell producing the so-called female sex hormone (folliculin or theelin). It is not surprising therefore that the hormonal effects produced by tumors of this variety are along the lines of feminization with overaccentuation of certain female sex characters and functions.

The Brenner tumor by contrast appears to exert no endocrine effect whatsoever and this presumably is due to the fact that its origin is related to an early undif-

From the Gynecological Department, Johns Hopkins Medical School. Because of lack of space the article is abbreviated in *THE JOURNAL*. The complete article appears in the authors' reprint.

ferentiated phase of development, the cells not functioning along either male or female lines. From such an early undifferentiated phase of the cells, likewise, there may arise still another type of tumor, the dysgerminoma (*grosszelliges Carcinom, seminoma*), which likewise exerts no effect on sex characters. This last group is observed chiefly in persons with defective

Fig 1—Folliculomatous or von Kahliden type of granulosa cell carcinoma (folliculoma ovarii). Patient aged 65 with pseudomenstrual bleeding and hyperplasia of the endometrium (see fig 2). This case has been previously reported by R. W. TeLinde (Am J Obst & Gynec 20:552 1930).

gonadal development, either male or female, so that it constitutes a rather characteristic tumor type in cryptorchids and pseudohermaphrodites. When dysgerminomas occur in pseudohermaphrodites, however, they are not to be interpreted as the cause of the intersexuality, in which respect they differ from still another group of tumors the arrhenoblastomas, to which reference will be made later and which may actually produce conditions of intersexuality.

To return to the granulosa cell tumors there is no doubt that they are far more frequent than the number of cases thus far reported would lead one to believe. Not many more than a hundred cases are now recorded, but a resurvey of the material in any laboratory would, if our own experience can be taken as a guide, disclose a great many more. In a recent restudy of our old material, we have already found no less than twenty-six cases of granulosa cell tumor, including those which we have had in more recent years, since we have learned to recognize such tumors more readily. In former years these tumors were classified variously under such heads as sarcoma, carcinoma and endothelioma. We shall not in this paper present any analysis of our cases, reserving this, with a fuller discussion of the general subject, for a later contribution.

These tumors may occur at any age, but are most common in women beyond the menopause. This lends support to the view that they can scarcely arise in the fully developed follicular apparatus, as Meyer has emphasized. When the tumors arise in elderly women, as they most often do, they produce a remarkable effect on the uterus through the endocrine action of the granulosa elements. The uterus becomes characteristically increased in size, and pseudomenstrual bleeding is noted, so that in some cases women far beyond the menopausal age exhibit an apparent reestablishment of the menstrual

function. This sequence must therefore be kept in mind as a possible explanation of postmenopausal hemorrhage. If, for example, diagnostic curetting in such cases shows no suggestion of malignancy, but on the other hand reveals a typical hyperplasia of the endometrium, the first thought should be of granulosa cell tumor of the ovary (fig 2). Indeed, some German authors suggest that, even if no tumor of the ovary is palpable, laparotomy may nevertheless be advisable, so characteristic is the association of hyperplasia, periodic bleeding and granulosa cell tumor at this age.

The hyperplasia in such cases is unquestionably due to the excessive production of folliculin by the granulosa cells, just as hyperplasia in women of the reproductive age is due to hyperfolliculism. That this is true has been confirmed, in a few cases, by the estrus effects produced in castrated animals by implantation of bits of such tumors, as well as by studies on the hormones of the blood and urine.

In at least a few cases, granulosa cell tumors have occurred in young children, and, in these, the hormonal effects are even more remarkable. The hyperfeminizing influence of these neoplasms is shown by the fact that in young children precocious puberty and menstruation are produced, together with such secondary sex characters as mammary hypertrophy, the growth of genital and axillary hair, increased growth, the development of the typical feminine postpuberal contour and increased size of the uterus to or almost to puberal size. Three such cases have been hitherto described, and three more have been added by one of us (Novak) in a recent paper.⁸

Granulosa cell tumors are commonly unilateral, and they vary in size from that of a hickory nut to perhaps that of a grapefruit, though both smaller and larger tumors have been described. The surface is smooth,

Fig 2—Typical hyperplasia of the endometrium from the case with an ovarian tumor shown in figure 1.

but the tumor may be somewhat lobulated. On section it is soft, sometimes granular, often with gelatinous areas, and, especially if the tumor is large, cystic cavities are seen, sometimes small, sometimes quite large.

The microscopic picture is variable, thus explaining the confusion in classification. Without reviewing the

whole question, two chief types can be distinguished. One of these is the folliculoid type (folliculoma) corresponding to the tumor originally described by von Kahliden and therefore commonly spoken of in the literature as the Kahliden type. In this there are large, well encapsulated collections of small round or polyhedral cells, morphologically resembling the normal granulosa cells, and showing somewhat similar growth character-

Fig 3—Granulosa cell carcinoma of diffuse variety

istics (figs 1 and 2). There is a tendency to the formation of tiny cystic cavities strongly suggestive of the so-called Call-Exner bodies so frequently seen in the granulosa of various animals, especially the rabbit. More extensive cystic areas are also frequently seen. The radiating growth tendency of the granulosa epithelium is well shown in the smaller cystic areas, for the cells are placed radially about these. Around the folliculomatous nests there is often a theca-like layer of connective tissue, so that the suggestion of a follicle-like structure is all the stronger, and it was this which led to the former view that these tumors arise from fully developed follicles of the ovary.

Much more common than the folliculoid type is the group which collectively may be spoken of as the non-folliculoid, although various subdivisions have been made (fig 3). Division cannot be made sharply, however, for different pictures may be encountered in different parts of the same tumor. In some cases there is a typical sarcoma-like appearance, and, at times, such areas cannot be distinguished from sarcoma (fig 4). In practically all cases, however, there is evident a tendency for the cells to arrange themselves in cords or tiny follicle-like nests. Often the granulosa cells are divided into long cylindric masses by numerous hyalinized trabeculae of connective tissue producing the cylindromatous type of tumor (fig 5). The cells usually show little evidence of anaplasia, though in some cases this is present. The tumors are as a rule quite vascular. In some instances, as already stated, typically sarcomatous areas are observed, which is not surprising if, as is now the trend, one accepts the view that the granulosa is of mesenchymal origin. The recent work of Fischenel has yielded strong evidence of the probable correctness of this view, as will be discussed later in this paper. On this basis certain sarcomatous tumors of the ovary may even be expected to exert female hormonal effects.

I have said nothing as yet as to the degree of malignancy of this group of tumors, and have thus far avoided the term granulosa cell carcinoma, by which they are most often designated in the literature. As a matter of fact, the degree of malignancy is in most instances very low, and recurrences are exceptional, even after removal of only the affected ovary. In some cases of this type it would seem better, especially in view of the absence of microscopic malignancy characteristics of the tumor cells, to speak of such tumors as granulosa cell adenomas, using the term adenoma in the broad sense in which it has been adopted for "adenomas" of other endocrine structures, such as the pituitary and the suprarenal glands.

In a certain proportion of reported cases, however, the tumors have run a distinctly and at times extremely malignant course, with recurrence, metastasis and death. Such a course has been noted in between 5 and 10 per cent of the reported cases. An instance of this sort has been only recently reported by Soltmann, and we have recently had one such malignant tumor in our own laboratory. This case will be reported in the near future by Dr. James N. Brawer. To judge from this single experience, however, the microscopic appearance in the malignant cases may differ definitely from that in the more common ones of more favorable type, for in our case there were obvious microscopic evidences of malignancy in the cell characteristics of the tumor. For such tumors the designation of granulosa cell carcinoma would be proper on both microscopic and clinical grounds.

ARRHENOBLASTOMAS

Much less common, but perhaps even more interesting, is a group of tumors which at times produces effects on sex characters almost diametrically the opposite of those resulting from granulosa cell tumors. Whereas the latter exert a hyperfeminizing influence, the others have a defeminizing or masculinizing effect. Before

Fig 4—Sarcoma like picture often seen in granulosa-cell carcinoma. Other areas in this same tumor show a much more typical structure.

discussing this group of tumors, a brief reference to the embryology of the ovary and to the factors concerned in sex differentiation seems indispensable.

Factors Concerned in Sex Differentiation—There is no more fascinating problem than that of the differentiation of the two sexes. That the sex of the offspring is determined by the chromosomal variations of the germ cells, more particularly those of the spermatozoon,

is now generally accepted. The presence of the single X chromosome on the one hand, or of the two X chromosomes on the other, apparently determines the male or female direction of zygotic development. In addition to this, biologists are coming to believe that the balance between the sex chromosomes and the autosomes is of great importance as well.

In the differentiation of the characters which are commonly associated with maleness or femaleness, however, the problem extends itself in a broad and as yet somewhat confusing way. Indeed, it involves such an extensive knowledge of biology as to put it beyond the ken of most medical men. And yet from this confusing mass of biologic knowledge certain simple facts appear to be crystallizing out, and many of them are of importance to the pathologist and the endocrinologist.

When one thinks of a male human being one visualizes a person with certain characteristic sex attributes, not only of external and internal genitalia, but also of body contour, distribution of hair, voice and the like. Similarly, the female connotes in one's mind certain fairly well defined "feminine" attributes. Are these

Fig. 5—Cylindromatous pattern common in granulosa cell carcinoma, and due to trabeculation by hyalinized connective tissue.

all to be explained by the initial impulse emanating from the male or the female zygote? The evidence is clear that in the higher forms this is not the case. In the case of certain lower forms, such as the insects, it seems to be true that the germ cell impulse is the all-important one. But in the higher forms and especially in the vertebrates, this initial zygotic impulse certainly cannot be so completely dominant, as shown by the variations of sex characters produced by castration, experiments on parabiosis or certain tumors of the endocrine glands.

Is a female, therefore, a person with a primarily female zygote, one with an ovary, or one with the physical and psychic characters which one associates with woman? Studies in intersexuality have shown that female external characters may dominate when the only gonad present is a testis, with no ovarian tissue at all. This is a clear refutation of Virchow's dictum that "solely on account of the ovary, woman is what she is" (*Propter ovarium solum mulier est quod est*).⁹

There is no longer any question that the endocrine glands constitute the immediate force behind the differentiation of the characteristic attributes of the two sexes. A wealth of biologic observations in many species sup-

ports this statement. The most important of the earlier observations on this point were those of Lillie⁹ in 1916. In cases of twin pregnancy in cattle, when one twin is male and the other female, the latter develops intersexual characters because of the early anastomosis between the circulations of the two twins. The studies of these intersexual twins, or "free martins," have been followed by numerous observations on other species. In certain toads, which are characteristically hermaphroditic, it is possible to produce development along either male or female lines by artificial means, such as variations in temperature.

It would lead us too far afield to adduce other observations indicating the importance of the endocrine glands in the differentiation of sex, but one more example will be cited because of its pertinence to our immediate subject. In fowls, which characteristically possess one active gonad, the other remaining rudimentary, it has been found that removal or destructive disease of the active ovary may be followed by active development of the rudimentary gonad, but along testicular or male lines. There is thus produced a complete reversal of sex characters, so that, as in the case of Crew,¹⁰ a hen which had been the mother of many chicks later grew a comb, developed other male characters, and even became the father of other chicks. Minor degrees of this intersexuality of fowls explain the phenomena of "crowing hens" and "egg-laying" roosters. For the reader interested in further observations of this sort, reference may be made to the book recently published by Allen, "Sex and Internal Secretions,"¹¹ and especially the chapters by Witschi, Danforth and Lillie.

Each zygote, therefore, is primarily bisexual, so that in each woman there are rudimentary homologues of many male structures, and vice versa. Of these the one which most concerns us now is the rete ovarii, which is not a mere analogue, but the actual homologue of the male testis. To put it another way, every woman shelters within the medulla of the ovary a potential testis. Under certain conditions this undifferentiated male tissue may become active, and its male endocrine influence may override the primary female tendency, with the production of various degrees of intersexuality. This, at any rate, is the point of view supported by most of the available evidence, so that I shall not discuss other theories, such as that of Halban,¹² who believes that the zygote is primarily male, female or hermaphroditic, and that the gonads exercise only a "protective" and not a "formative" influence in sex differentiation.

To summarize, therefore, the primary sex differentiating force originates from the zygote produced by the union of the male and female germ cells or gametes. In the higher forms, however, this can be modified or overridden by the endocrine influence of the gonads and other affiliated glands. It should be added that the zygotic influence is believed to determine whether the gonad is to be an ovary or a testis, so that, in the final analysis, a single motivating force is behind the whole differentiating process. With this briefly sketched review of the factors concerned in the differentiation of sex characters, we can more intelligently discuss the second group of ovarian tumors, associated as it is with modifications of sex character.

Arrhenoblastoma of the Ovary—In 1905, Pick¹³ described a tumor of the ovary made up of convoluted tubules resembling the seminiferous tubules of the testis, and he therefore designated this tumor as adenoma testicularis (tubulare) ovarii. A second case of the same type was described in 1907 by Schickele,¹⁴ who accepted Pick's view that the tumor formation occurred in the testicular portion of an ovotestis. This view was held in spite of the fact that neither patient had previously exhibited any hermaphroditic manifestations. Other tumors which were later reported by Neumann¹⁵ and Meyer¹⁶ presented a more atypical testicular pattern, and to these Meyer applied the name "adenoma testiculare ovarii partim carcinomatosum."

Only a small group of cases of the type of Pick's "adenoma tubulare testicularis" have been observed, and in only about one-third is there any clinical evidence of an influence on sex characters. There are other types, however, which exhibit a much more atypical and, in some cases, sarcoma-like pattern, instead of the mature testicular tubules characterizing the typical testicular adenoma of Pick. In this atypical variety manifestations of defeminization or masculinization of the patient are the rule. An intermediate form has been shown by Meyer to exhibit an intermediate degree of effect on sex characters. It may at first seem strange that sex changes are found so much less frequently with tumors made up of fairly mature testicular tissue than those in which the testicular tissue is extremely undifferentiated, unless one stops to think that in some cases of pseudohermaphroditism, in which the secondary sex characters are altogether female, the only gonads present are testes and not ovaries.

The histogenesis of these tumors, according to Meyer, is to be sought in certain undifferentiated cells persisting in the rete, and capable of later function along either male or female lines. The masculinizing group of tumors, or arrhenoblastomas, develop in the potentially testicular cells present in the rete ovarii, and through their hormonal effects override the feminine influence of the ovary.

Meyer's explanation appears to have been rather widely accepted, although, until more is known concerning the factors involved in normal and abnormal sex differentiation it must be looked on as an excellent working hypothesis rather than as a demonstrated fact. A point which, it seems to us, has not been sufficiently stressed is the fact that the medulla of the gonad is a determiner of masculinity and the cortex of femininity of their contained germ cells. This observation, championed especially by Witschi, is based on excellent biological evidence. It is therefore not surprising that tumors arising in the ovarian medulla should exert a masculinizing influence. Incidentally, it is suggestive that cortical tumors of the suprarenal gland, which embryologically is so closely associated with the ovarian medulla characteristically produce syndromes similar to those seen with arrhenoblastomas.

The clinical manifestations of these tumors vary according to the degree of their masculinizing hormonal influence and this in turn appears to be a reflection of the degree of undifferentiation of the tumor cells. In the most extreme cases the woman who has previously been of normal feminine type becomes amenorrheic the

breasts flatten and atrophy, a heavy growth of hair appears over the face, chest, abdomen and lower extremities, the figure loses its normal feminine curves and assumes the typically more angular contour of the male, and the voice becomes much deeper, owing to laryngeal hypertrophy. The clitoris may show such hypertrophy as to be almost penis-like in its proportions.

Such symptoms, occurring in a patient who has developed an ovarian tumor, should lead to the suspicion that one is dealing with an arrhenoblastoma. Removal of the tumor leads to a regression of the symptoms, thus establishing its causative role. In at least one reported case, that of Kleinhaus,¹⁷ such a syndrome was noted, and, further to establish the direct hormonal influence of these tumors, a reappearance of the symptoms was observed when a similar tumor recurred in the other ovary. Certain of the symptoms, it is true, may persist for a long time after operation, such as the hypertrophy of the clitoris, but in all reported cases the refeminization of the patient has been so striking as to leave no doubt as to the role played by the tumor.

In tumors of the intermediate type, of which a considerable group have been observed, the symptoms are

Fig 6—Arrhenoblastoma from the case reported by Taylor, Wolfemann and Krock, who allowed us to use this tissue for study, and gave us permission to use this photomicrograph. This patient showed amenorrhea, flattening of the breasts, striking masculine hirsutism with a heavy growth of beard, the development of masculine body contour, a deepening of the voice and marked hypertrophy of the clitoris.

much less marked. In some instances only amenorrhea may be noted, in others, amenorrhea with more or less hypertrichosis, and so on, depending on the intensity of the hormonal effects of the tumor.

Tumors of this general group are usually unilateral, and, like most tumors of this embryonic group, are of a relatively low degree of malignancy. They are commonly of moderate size, ovoid and perhaps lobulated, of soft consistency, and not infrequently of yellowish color on section.

The microscopic pattern is variable so that in former years they were classified under various designations, such as sarcoma, carcinoma or endothelioma. As already stated the typical testicular adenoma of Pick is an adenomatous structure made up of convoluted tubules. At the other extreme in the markedly atypical variety there may be little to suggest an origin from the same source, for in many places the structure is indistin-

guishable from a sarcoma. If a sufficient number of blocks are studied, one can always find a suggestion of tubular or strandlike arrangement of the cells, often suggesting the sex cords of early gonadal development. The cells themselves are most often rather spindle-shaped. In a number of instances another type of cells has been found scattered throughout the tumor, and these cells have been interpreted as interstitial cells.

Fig 7—Arrhenoblastoma of intermediate variety associated with amenorrhea, hypertrophy of the clitoris and deepening of the voice (see text)

In tumors of this general type, it is of the greatest importance to study tissue from all parts of the tumor, for the structure varies in different areas, and the real nature of the tumor may be overlooked unless the study is sufficiently thorough.

It may again be stressed that the pseudohermaphroditic symptoms which may be associated with these tumors are actually produced by them, for the patients are normal until the development of the tumor, and the pseudohermaphroditic symptoms disappear after removal of the tumors. In this respect these growths are quite different from the disgerminomas, which likewise may occur in pseudohermaphrodites, but which have nothing to do with the production of the bisexual condition.

While in this paper we have stressed particularly Meyer's explanation of the masculinizing tendencies of these tumors, it cannot yet be assumed that it is the correct one. The problem will not be solved until many more cases have been carefully studied, and until more is known concerning the mechanism of sex differentiation and the causes of intersexuality. The fact that suprarenal tumors may likewise produce masculinization phenomena makes the study of cortico-ovarian interrelations one of great importance in the elucidation of these problems. The fact that ovarian tumors of types other than those discussed in this paper have appeared at times to produce similar manifestations must also be explained. The great value of Meyer's contributions is in having called attention to this rare but biologically important group of tumors, and in having offered what appeared to be an excellent working theory of their histogenesis and their pathologic physiology.

Only a small group of these tumors, twenty-eight of all three grades, has been reported, but with the newer interest in the syndrome, there is little doubt that the

number will be rather rapidly augmented. So far as we know, only four cases have thus far been noted in the literature of this country. The first appears to have been that of Moots,¹⁸ in 1921. The pathologic diagnosis in this case was "fibroblastic sarcoma of embryonic testis, possibly of ovotestis." The photomicrographs and the description of the microscopic findings leave no doubt as to the propriety of including the tumor in the group of arrhenoblastomas, and the clinical picture was equally typical, the patient developing amenorrhea, hypertrichosis, a deep voice and enlargement of the clitoris. All of these manifestations regressed after removal of the tumor of the left ovary.

Popoff's case (1930)¹⁹ was reported as a testicular tubular adenoma of the ovary, and Meyer has since then included it in the intermediate variety of arrhenoblastoma, although amenorrhea alone was apparently the conspicuous symptom, without the masculinization manifestations seen with the more atypical tumors. A third case has recently been reported by Spielman,²⁰ and is likewise to be classed as of the intermediate grade. The fourth case has been observed by Taylor, Wolferrmann and Krock,²¹ and has just been published. Through the kindness of Dr. Krock, we were able to study tissue from this tumor (fig. 6), and sections were likewise examined by Prof. Robert Meyer, who concurred in the diagnosis. Dr. Krock has also permitted us to include in this paper an illustration of the characteristic microscopic picture. The tumor in this case is obviously of an atypical variety, and hence, as might be expected, the symptoms of masculinization were of high grade.

We are able to add a fourth case discovered in our search through our old material. Such retrospective study of cases is not nearly as satisfactory as might be wished, for the histories of many years ago, apart from incompleteness in other respects, took little cogni-

Fig 8—Another area in the same tumor showing a sarcoma like picture with numerous cordlike groups of cells reminiscent of the early sex cords.

zance of endocrine manifestations, which in more recent years would have excited interest and comment. Furthermore, the original tissue is often unavailable for more extensive study, as in this instance. Our case,

which will be more fully reported later, was that of a patient, aged 20, who was operated on in 1898 for a rather large abdominal tumor of long duration. She had not begun to menstruate until the age of 18, when two normal periods occurred, about one month apart. There had then been amenorrhea for thirteen months, at which time (July, 1898) a scanty period had occurred. Following this there was again complete amenorrhea until she entered the hospital in October. Her voice was described as "harsh and rough," and the clitoris is said to have been markedly hypertrophied. Unfortunately, no note was made of the distribution of hair.

The operation revealed a tumor of the left ovary, which was later diagnosed as an adenocarcinoma. Our recent reexamination convinces us, however, that the tumor belongs to the group of arrhenoblastomas. In some areas a definite tubular structure is preserved, while in others the tumor presents a fairly typical picture of sarcoma as will be seen from figures 7 and 8.

Following the operation, regular menstruation occurred in December, January and February, but in the latter month examination showed recurrence of the tumor, with pain, ascites and emaciation. At a second exploratory operation, the condition was considered hopeless, and only a biopsy of the recurrent tumor was done, with evacuation of the ascitic fluid. The patient declined rapidly, being discharged from the hospital on March 28, presumably to die. The rapid recurrence of the tumor in this case is in contrast with the low degree of malignancy noted in most cases, and is perhaps explainable by the long duration of the disease before the patient came under observation.

SUMMARY

The observations in this paper are based on the study of material from twenty-six cases of granulosa cell ovarian tumors and two cases of arrhenoblastoma, together with a number of other cases of other tumors of this embryonic class particularly disgerminoma (seminoma) and the so-called Brenner tumor (oophoroma folliculare). The especial points stressed have been (1) the feminizing tendency of the granulosa cell group, dependent on the production of folliculin by the constituent cells, and (2) the defeminizing and masculinizing tendencies of the arrhenoblastomas. The latter capacity is believed to be due to the origin of the tumors from certain undifferentiated cells in the region of the rete ovarii, which is the female homolog of the testis. The intersexual phenomena which may be brought about by these rare tumors are of great biologic interest, especially as they are not unlike the phenomena which may be observed with certain lesions of the suprarenal cortex. An additional case of arrhenoblastoma is reported, and there is a brief discussion of the factors concerned in sex differentiation, for without some knowledge of this still somewhat nebulous subject the pathologic physiology of these tumors cannot be intelligently studied.

ABSTRACT OF DISCUSSION

DR RICHARD W. TELINDE, Baltimore. Knowledge of the histogenesis of some of the rarer types of ovarian tumors has come about from the fact that they are composed of tissues which are active from an endocrine point of view or that they are acted on by the endocrine secretion of other glands. For instance it is concluded that the so-called chocolate cysts of the ovary are histogenically related to endometrial tissue because

they respond to the ovarian hormones similarly to the endometrium in the uterus. As to the origin of the masculinizing and feminizing tumors described by the authors is obtained from the fact that they apparently produce a hormone secretion that influences the genital organs themselves and changes the secondary sexual characteristics of the individual. The more common tumors such as cystomas and cystadenomas are silent from an endocrine functional point of view and hence practically nothing of their histogenesis is known. As has been suggested, these feminizing and masculinizing tumors are not as rare as heretofore believed. I saw three granulosa cell tumors in the course of one year. A better idea of the histogenesis of these tumors may be obtained from studying the early cases rather than the late ones. A few years ago I found a very small but typical granulosa cell tumor, only about 3 mm in diameter, in the hilus of the ovary. Adult follicles do not normally occur in the hilus of the ovary, but this part of the ovary is a hot bed of embryonal rests. Therefore, the finding of this small tumor in this position would seem to indicate strongly its origin from an embryonal rest of granulosa cells rather than the adult follicle. Dr Novak spoke of the work of Fischel on the embryology of the ovary in which he concludes that the follicular epithelium of the ovary is derived from the mesenchyme of the primordial sex gland. Further support of this view is suggested by the fact that certain tumors which histologically appear sarcomatous have the same feminizing effect as the granulosa cell tumors. A sarcoma of the ovary was removed from a 13 year old child who showed excessive development of the breasts and pubic hair and a uterus as large as an adult's. She bled approximately half the time since the onset of her menses at 11, and curetting showed hyperplastic endometrium. Removal of the tumor caused the patient's menses to become regular in tempo and duration.

DR FRED KROCK, Fort Smith, Ark. The origin of the causative factors for the development of the secondary sexual characteristics of the body is probably exceedingly complex. Extragonadal tumors, such as the basophilic adenomas of the pituitary, and carcinomas of the suprarenal cortex, have been shown to effect such changes even in the adult, with the gonads playing a secondary role. Each of the two types of functioning ovarian tumors presented by the authors is undoubtedly exposed to the same hormones from presumably normal pituitary, suprarenal and other endocrine glands, with excessive femininity, precocity or rejuvenation resulting in the cases of granulosa cell carcinomas and a defeminization and masculinization with the arrhenoblastomas. These changes are apparently due to the carrying over of the physiologic activity of the tissue from which the tumor is derived into the tumor itself. The interstitial cells of the testis which embryologically are modified connective tissue cells, are considered to be responsible for the development of the secondary sexual characteristics of the male. It has been observed that the atypical type of arrhenoblastoma which morphologically is predominantly sarcomatous exhibits clinically the most marked and constant masculinization. On the other hand pure ovarian sarcomas, which occur not uncommonly, have never been observed to have been associated with changes in the secondary sexual characteristics. It is therefore tenable that these changes are due in the arrhenoblastomas to the elaboration of a large amount of this male growth directing hormone by what are potentially interstitial cells or their anlagen modified by neoplastic development. In the case recently reported by Taylor, Wolfertman and Krock three competent pathologists made the diagnosis of sarcoma of the ovary before further study. Verified by Meyer demonstrated epithelial testicular elements in the tumor. The patient experienced a complete return to normal femininity after operation. Fifteen months later recurrent nodules removed from the omentum showed on section spindle cell sarcoma and areas of cartilage like tissue. This brings up the question as to whether or not arrhenoblastoma of the ovary is a pathologic entity or whether it is merely a modified teratoma in which growth of functioning sex-directing cells has taken place at the expense of the other tissue elements usually found in these tumors. It also shows that these tumors are more malignant than is usually considered.

DR. EMIL NOVAK, Baltimore. I am glad that Dr. Krock brought up the question of sex differentiation, which I have discussed quite fully in the paper, although I had not time for this in the short summary which I had presented. There is no question as to the importance of the role played by the endocrines in the higher forms of animal life, although the primary impulse toward differentiation along male or female lines undoubtedly emanates from the germ cell itself. In the discussion of the pathologic physiology of these tumors I presented particularly the view advocated by Meyer, but knowledge of the whole subject is still so incomplete that this view is not to be accepted too wholeheartedly as yet. However, it does constitute by far the most acceptable working hypothesis available.

A PLASTIC OPERATION FOR CERTAIN TYPES OF HEMORRHOIDS

W. A. FANSLER, M.D.
AND
JAMES K. ANDERSON, M.D.
MINNEAPOLIS

If hemorrhoidectomies are to be done with uniformly good results, the method of procedure must be varied to suit the condition that presents itself. No one operation is equally satisfactory for all cases. This procedure is suggested for a certain type of case, namely,

Fig 1—Prolapsed ring of thrombotic internal hemorrhoids with thrombosis of anal and external hemorrhoids and eversion of anal canal

that in which there is a complete prolapse and thrombosis of the entire ring of internal, anal and external hemorrhoidal vessels (fig 1). This condition presents itself as a bluish doughnut-like ring surrounding the anal opening, the doughnut being covered by the prolapsed anal mucosa and perianal skin, which of course, is squamous in character. Inside this "doughnut" are several prolapsed and thrombotic internal hemorrhoids covered with a moist columnar type of rectal mucosa. A definite constriction or sulcus separates these two protuberances. This sulcus is the pectinate line and represents the upper limit of the anal canal when the anal mucosa is in its normal position.

If this entire prolapsed mass is removed, the victim is left with an anal canal lined with rectal mucosa which secretes mucus so that he will have a moist anus with excoriation of the perianal skin and soiling of his underwear for the rest of his life. This postoperative condition has been termed by Dr. Dudley Smith of San Francisco the Whitehead deformity. It is with the idea of preventing this deformity and its attendant

inconveniences that the procedure presented here was evolved. The purpose of the operation is to remove the thrombotic and varicose hemorrhoidal vessels and to restore the normal lining and appearance of the anal canal. The basic principle involved is developed from

Fig 2—Anal canal retracted exposing junction of squamous and columnar epithelium (the pectinate line)

the true Whitehead operation, as is likewise the "amputative operation" done by Dr. L. A. Bute.

Any type of anesthesia may be used, though our preference in the majority of cases is spinal, produced

Fig 3—Line of incision completely round the pectinate line

by the use of from 35 to 50 mg. of procaine hydrochloride dissolved in from 1 to 15 cc. of spinal fluid. The patient is placed on the table face downward with the hips elevated either by the use of a hard roll of blankets or a mechanical elevator, if one is available. The field is cleansed with 50 per cent alcohol. The

outer ring is retracted and the sulcus dividing the squamous from the columnar epithelium exposed (fig 2). The internal portion of one of the hemorrhoids is grasped and an incision made at the juncture of the two types of mucosa (figs 3 and 4). The outer margin of the incision is grasped with Allis forceps and the mucosa and skin dissected outward as far as the normal skin. This leaves a long flap of free anal mucosa and skin. On the internal portion of the hemorrhoid the thrombotic tissue is dissected upward as far as the margin of normal mucosa. This tissue is removed. All other thrombotic vessels are now dissected out until the sphincters are exposed. This process is repeated around the entire anal circumference. When it has been completed, the anus is surrounded by several flaps of skin which are attached at their outer borders, and an inner ring of normal rectal mucosa presents itself at the lower margin of the anal canal. Any spurting vessels appearing during the operation are

Fig 4—Anal mucosa retracted and all thrombotic vessels dissected away from it

ligated with plain 00 catgut though, as a matter of fact, there is surprisingly little bleeding.

The rectal mucosa is allowed to retract and a Fansler operating speculum is inserted into the anus. Two sutures of 00 chromic catgut are passed through the outer margin of one of the skin flaps and needles are left on the sutures. The rectal mucosa is grasped with Allis forceps at a point directly internal to the anal flap. The sutures attached to the skin flap are now passed through the rectal mucosa and a portion of the rectal wall at a point representing the normal anorectal margin. These sutures are then tied, this portion of the anal canal being thus restored to its normal state (fig 5). The same process is repeated about the rest of the anal canal, usually four or five flaps being utilized to complete the procedure. The completed operation shows a normal appearing anus except for four or five lines of incision (fig 6).

The patient usually leaves the hospital in six or seven days. After healing it is almost impossible to tell that

any operative procedure has been done. The only difficulty encountered is when a skin flap fails to adhere and everts down. In this case it should be excised or a permanent skin tab will result. In case all the flaps

Fig 5—Restoration of a flap of anal mucosa to its normal position

should loosen, it would be necessary to do a secondary replacement, otherwise a stricture might result. I believe that the use of chromic gut obviates this danger, for in our series of cases this has never happened, though in one case one flap did not adhere and was

Fig 6—All flaps of anal mucosa restored. Operation completed

excised. I believe that in this type of case several flaps are better than a continuous suturing of the entire circumference of the anal and rectal mucosa, because there is room for drainage between the flaps for whatever infection that may develop. Also it allows for drainage or any oozing so that no large hematoma may form and it permits the removal of any redundant folds or tabs of mucosa, thus insuring a better cosmetic result.

74 South Ninth Street

ABSTRACT OF DISCUSSION

DR CLEMENT L. MARTIN Chicago To attempt to discuss an operation one has never done nor even seen performed offers certain difficulties. A priori, the operation is logical and is based on sound anatomic and surgical principles. Except for the radiating linear skin incisions, it is the same in effect as the Whitehead operation. That it might be followed in the occasional instance by some degree of stricture at the line of suture where skin is joined to the mucosa strikes me as a possibility. The case of separation and retraction of a skin flap mentioned by the authors indicates another possible source of trouble. However, one is justified in assuming some risk to cure the type of cases in which the authors advocate the operation. The group is a difficult one seen more frequently in the dispensary and charitable institution work, the severe cases of prolapsed generally thrombotic internal hemorrhoids with a veritable collar of skin around them, often with a ring of varices lying underneath that skin and at times with edema and inflammation of the skin. They present a real surgical problem and I hope that the procedure may make my own tasks less difficult. That no single type of hemorrhoidectomy is applicable to all cases should be much more generally understood.

DR LOUIS J. HIRSCHMAN Detroit The authors have devised an operation which will save a great deal of that valuable covering which in the minds of many people, seems to be the principal part of the hemorrhoid. Too often in the removal of hemorrhoids the surgeon has removed everything that he can see protruding or which seems enlarged and as a consequence, many hemorrhoidectomies resolve themselves into removal of large masses of perfectly innocent and healthy skin and mucous membrane while the essential pathologic condition, namely, the diseased veins is left behind. This operation differs from the Whitehead operation as it is performed by many surgeons. The results of these present themselves for correction later. Most of the Whitehead deformities that I see are evidenced by eversion of mucous membrane due to the fact that too much skin has been taken away. With the operation described by Drs Fansler and Anderson much of that has been avoided. I believe with Dr Clement Martin that in occasional instance of annular contraction may occur where the flaps are sewed to the mucous membrane. One can avoid this complication by not separating the skin from the mucous membrane but by making three elliptic flaps estimating beforehand the amount of tissue to be removed to allow a sufficiently wide isthmus in the three instances between the flaps. This will completely restore the normal caliber of the bowel. These isthmuses are composed of skin and mucous membrane. To dispose of the varicosities or thromboses, which make up a large part of the bulk of the large, rolled out "doughnuts," one can remove all pathologic tissues between the skin, mucous membrane and sphincter, and leave the membrane intact. As the wound heals, there may be a little redundant skin at the outside, which may have to be removed later but there is no danger of a stricture because there has been no separation of the continuity of skin and mucous membrane.

DR W. A. FANSLER Minneapolis I was interested in what Dr Hirschman said about leaving the islands of skin and then undercutting them. I learned this from Dr Hirschman several years ago and have employed it many times but I do not feel that it serves the purpose in this type of case. I have had no trouble so far with strictures forming in these cases. The reason I divide the mucous membrane of the anus from that of the rectum is that it does not leave any skin tags on the outside. The most common site for strictures following operations about the rectum is in the anal canal. I think it is seldom that one encounters a stricture of the rectum itself following operations. In the operation described in this paper if one uses long flaps of skin and stitches their upper margins well above the upper end of the anal canal and into the rectum itself, one will avoid stricture.

The Drop in Diabetic Coma—Who would have believed that mortality from diabetic coma would drop from 60 per cent to 5 per cent in seventeen years? Arteriosclerosis now causes more than half of all diabetic deaths—Joslin, E. P. *New England J. Med.* 209:519 (Sept. 14) 1933.

Clinical Notes, Suggestions and
New Instruments

A UNIVERSAL BONE RONGEUR

PHILIP LEWIN, M.D., CHICAGO

The new instrument here described has been found useful in a large variety of operations on bones and joints. The mechanical principle on which the instrument is based was suggested to me about eight years ago by the late Dr. George

Marshall of Kokomo, Ind., who made, by hand, his original model for hammer toe operations.

I have found this rongeur valuable in the operations of laminectomy, cheilectomy, hallux valgus, hammer toes, spine fusion, shaping and cutting bone grafts, arthrodesis of the foot and biopsy.

The instrument is used more and more in situations in which I formerly used an osteotome, chisel, punch or rongeur. Some of the advantages of this instrument are that (1) it is almost universal in application, (2) the operator can cut bone to an accurately desired depth, (3) it will cut the hard dense cortex of the tibia or femur and the soft cancellous bone of a meta-

Universal bone rongeur

carpal or metatarsal, (4) it does not crush the bone but cuts it as a microtome cuts a section of tissue, (5) it has a box lock which prevents overriding of its jaws, (6) it does not produce shock as does mallet and chisel, (7) it is self-cleansing because the cut bone is forced through the open jaws.

The instrument is made in two sizes.

The manufacturer, V. Mueller & Co., Chicago, aided greatly in the development of this instrument.

NICKEL DERMATITIS FROM SPECTACLE FRAMES
AND WRIST WATCH

HOWARD FOX, M.D., NEW YORK

Two years ago, Lain reported¹ three cases of dermatitis due to spectacle frames made of white gold, an alloy containing nickel. Since then I have seen a patient who had not only a similar dermatitis from spectacle frames but also an eruption due to wearing a nickel-plated wrist watch.

E. G., a man aged 24, a clerk, consulted me March 10, 1932, for a vesicular and crusted eruption limited to areas where his spectacle frames were in contact with the skin. The affected areas included horizontal streaks along the temples and small patches on the ear lobules, the postauricular region and the left inner canthus. He also presented well-defined erythematous squamous patches on the front and back of the right wrist corresponding to the position where his wrist watch had been in contact with the skin.

The patient had worn spectacles since childhood for near-sightedness. He had always used spectacle frames made of tortoise shell until six months before when he changed to frames made of "white gold." About six weeks before I saw

¹ Lain, E. S. Nickel Dermatitis. *A New Source*. J. A. M. A. 96:771 (March 7) 1931.

him he noticed that the rims of the spectacles were beginning to tarnish and a week later the eruption appeared on his face. This disappeared completely in three or four weeks after he discontinued the use of the white gold frames. When seen a year later, the eruption had not recurred.

The patient had also worn a nickel-plated wrist watch for the first time in his life during the past ten months. At the

Fig 1—Dermatitis due to spectacle frames of white gold

end of four or five months an eruption appeared on the back of the right wrist, and the patient noticed that a good deal of the nickel plate had become worn. He discontinued wearing the watch and the eruption promptly disappeared. One month later he again wore the watch on the back of the wrist and for the second time an eruption appeared in this locality. He

Fig 2—Dermatitis due to nickel plated wrist watch

changed the watch to the front of the wrist and this was also followed by an eruption confined to the area where the watch had been in contact with the skin. He stopped wearing the watch entirely but since that time (three months) the eruption had persisted on both the back and the front of the wrist. He was given three fractional doses of unfiltered x-rays at weekly intervals with moderate improvement. He then disappeared from observation but when seen a year later (April 12 1933) he stated that the eruption on the left wrist had disappeared

one week or so after the last x-ray treatment and had not recurred.

It is well known that certain individuals are sensitive to nickel and after sufficient contact with this metal develop a dermatitis. This case is plainly one of contact dermatitis in such a person, as the eruption appeared at points of contact disappeared on removal of the causative agent and reappeared on subsequent contact. The persistence of the patches on the wrist simply indicated the high degree of sensitivity which repeated contact had produced.

140 East Fifty-Fourth Street

RESORCIN ANAL DERMATITIS DUE TO RESORCIN IN ANUSOL SUPPOSITORIES

JAMES H MITCHELL M D CHICAGO

Resorcin sensitization is encountered from time to time in dermatologic practice. What the percentage of sensitized individuals may be is unknown at present. Urbach¹ says that only one person in several thousand will be found sensitized and Nathan and Stern² state that cases of resorcin sensitization are rare.

Resorcin (metadihydroxybenzene) is an ingredient of many hair lotions sold in the shops and used by hair dressers and barbers. Examination of the prescription files of a pharmacy doing a large prescription business discloses that many prescriptions for resorcin are filled daily and that resorcin is prescribed

Fig 1 (case 1)—Positive patch tests from left to right 1 Pyrocatechin (orthodihydroxybenzene) (twenty four hour patch test) 2 Anusol suppository—resorcin (metadihydroxybenzene) (two weeks after twenty four hour patch test) 3 Hexylresorcinol (alkyl resorcin)

Orthodihydroxybenzene

Metadihydroxybenzene

about four times more frequently than is monoresorcinol acetate (introduced as Euresol).

An informal inquiry of some of the druggists doing a large volume of business in the Chicago loop district indicates that the sale of Anusol suppositories is heavy. No one interviewed, however, had had any complaint of irritation set up by the use of these suppositories. A report of two cases of severe dermatitis occurring in resorcin sensitized individuals as the result of the use of these suppositories therefore may be of interest. One of these cases was demonstrated at the April meeting of the Chicago Dermatological Society and photographs of the patch tests in both cases were shown at this session of the society.

CASE 1—A physician developed a mild hemorrhoid in September, 1932. Never before having had occasion to use or prescribe anal suppositories he had an ample accumulation of Anusol samples in the office. Curiosity as to the possible effect of anal suppositories on hemorrhoids led him to test the efficacy of the generous supply of samples. The suppositories were

¹ Urbach E. Arch f Dermat u Syh 118 146 1924
² Nathan E. and Stern F. Dermat Wehnschr 61 1471 (Oct) 1930

used as directed for three days. At the end of that time the itching and burning had become almost intolerable, but the hemorrhoid remained unchanged. The suppositories were discontinued, petrolatum was applied freely and, in the course of two weeks, the discomfort gradually disappeared.

A twenty-four hour patch test of the suppository on the arm resulted in a severe reaction, which lasted for three weeks.

Fig. 2 (case 2)—Positive patch test with Anusol suppository after twenty four hours (metadihydroxybenzene)

When a medical student, the patient had discovered as a result of application of resorcin to the scalp that he was highly sensitized to this drug. A patch test with hydroquinone (paradihydroxybenzene) gave a slightly less sharp reaction. A patch test with pyrocatechin (orthodihydroxybenzene) gave a sharp reaction but was perhaps slightly less than that of hydroquinone. A test with monoresorcinol acetate was about equal to that of hydroquinone. A patch test with hexaresorcinol gave a very slight but definitely positive reaction. A patch test with plain cacao butter was completely negative.

Fig. 3 (case 2)—Positive patch test with 0.4 per cent solution of resorcin after twenty four hours (metadihydroxybenzene)

CASE 2—A man a cosmetic manufacturer was first seen in January 1927, with a severe dermatitis about the anal region. He had consulted his family physician for a hemorrhoid. There had been no itching. He was referred to a dermatologist who instructed him to break an Anusol suppository into two parts, one of which was to be inserted and the other to be rubbed about the anal region. A severe pruritus developed. He deserted the dermatologist and consulted a proctologist, who discontinued the suppositories but added other irritants. At the height of the dermatitis the patient was seen by me. A treatment dermatitis was obvious but sensitization to the resorcin in Anusol suppositories was not suspected. The patient was given radiotherapy and soothing application, with complete recovery.

In April, 1927, the patient was again seen with a mild dermatitis as a result of the appearance of a hemorrhoid and the use of one Anusol suppository. The suppository was still not incriminated, but never having prescribed suppositories I dis-

continued them. The patient was not seen again until April 1, 1933, when he appeared with an area of dermatitis the size of his palm about the anal region. He stated that another hemorrhoid had developed and that he had applied and inserted the Anusol suppository as directed by the dermatologist in 1927. A patch test with an Anusol suppository gave a violent reaction. A patch test with resorcin gave a similar reaction. Patch tests with hydroquinone (paradihydroxybenzene) and with pyrocatechin (orthodihydroxybenzene) were exactly similar to those in case 1. The anal dermatitis subsided with soothing applications and discontinuance of the suppository.

Presence of resorcin in Anusol suppositories was readily determined by applying the United States Pharmacopoeial tests as follows. Two suppositories were dropped in 10 cc of boiling distilled water. The fat was filtered out through paper, the resulting clear liquid was tested as follows: a few cubic centimeters were mixed in a test tube with 10 cc. of sodium

Fig. 4 (case 2)—Positive forty hour patch test with pyrocatechin (orthodihydroxybenzene)

hydroxide test solution and a drop of chloroform added. Heating the solution resulted in an intense crimson solution. The same test carried out with a 1 per cent solution of resorcin gave a similar result. Tests carried out with solution of hydroquinone and pyrocatechin were entirely dissimilar. A few cubic centimeters were mixed with ferric chloride test solution. A violet color resulted. Adding ammonia test solution resulted in a deep brownish yellow solution. These positive chemical tests, together with the sharply positive patch tests, occurring in a known resorcin sensitized individual and in another individual who also gave a positive resorcin test, would seem to

Fig. 5 (case 2)—Positive forty hour patch test with hydroquinone (paradihydroxybenzene). The relic of the resorcin patch test is seen higher up on the forearm.

leave little doubt as to the presence of resorcin in the suppositories.

These two cases are of interest because of the lack of agreement in the observations of Urbach and those of Nathan and Stern. Urbach found that his patient also reacted to hydroquinone and to pyrocatechin. In other words, there was a group reaction to the isomers of resorcin. Moreover, internal administration of the drug caused a violent generalized eruption.

tion. Gradually increasing doses of the drug, however, resulted in desensitization. Nathan and Stern, on the contrary, state that their patient did not react to hydroquinone and to pyrocatechin. Their patient, however, did react to the monomethylether of resorcin but not to the dimethylether. Their patient therefore did not react to the isomers but did react to some of the derivatives of resorcin.

CONCLUSIONS

1 Two cases of severe resorcin anal dermatitis resulted from the use of Anusol suppositories.

2 The rarity of such cases seems to be indicated by the few references in the literature to resorcin dermatitis and to the absence of reference to cases of dermatitis due to this drug when used in suppositories.

3 My observations agree with those of Urbach and are contrary to those of Nathan and Stern as regards the reaction of resorcin sensitized individuals to the isomers of resorcin.

LYMPHOGRANULOMA INGUINALE, THE
FOURTH VENEREAL DISEASE

ITS RELATION TO STRICTURE OF THE RECTUM

H. N. COLE, M.D.

CLEVELAND

A disease known as climatic bubo has been, in part at least, recognized for the past seventy-five years. It was supposedly tropical in character, running a very chronic course with more or less suppuration of the affected inguinal lymph nodes. It was supposed to follow venereal exposure, especially to Negro women. The lymph node symptoms did not show up, as a rule, until an entrance for the infective agent was no more to be found. The cause was unknown. As long ago as 1865, the French clinician Trousseau¹ gave a very good description of it.

I must not forget to say a few words about a lymph node infection which I have often observed in the young Creoles, and more particularly in the Creoles of Reunion and Maurice.

In adolescence and more in the boys, we see the superficial and deep nodes in the groin swell up on one or both sides. Symptoms of the disease come on in cycles lasting one two or three months and separated by intervals, it may be, of several months. Then comes a violent paroxysm and several of the nodes suppurate. In certain of the cases the suppuration extends to several of the nodes or to the entire mass. The patient is thus bedridden for a long time and the suppuration may last for a year. In most of the cases the disease comes in the winter years.

Scheube² in 1867 while independently writing of this trouble as seen in Japan, gave it the name "climatic bubo." Jouet³ in 1882 in Indo-China, described a suppurating bubo not accompanied by a portal of entry. Particularly enough H. G. Klotz⁴ in 1890 reported that in a period of ten years' hospital practice in New York he had seen 120 cases of "strumous bubo," most of

them coming in the summertime. He felt that they had no relation to syphilis, though he had often noted the concomitant appearance of an erosion of a small sore, or of herpetiform lesions of the genitalia. He found that the lymph nodes in the groin were filled with milium pus foci, and he was astonished that so little was said about them in the literature.

Subsequent reports have been made on this disease by various writers, including Muller and Justi⁵ who, in 1914, reviewed the entire condition. In the United States various naval medical officers have, from time to time, written on the subject of tropical bubo. Hansmann⁶ recently reported several cases, using the term "nontuberculous lymphadenitis." Later Barber and Coogler used the same term in reporting cases. It remained, however, for Nicolas, Favre and Durand⁷ to describe fully and interpret correctly the clinical and histologic picture of this disease, which they termed "subacute inguinal lymphogranulomatosis" (lymphogranulomatose inguinale subaigue). They considered the origin venereal. They considered the small foci of suppuration disseminated throughout the parenchyma of the lymph node as very characteristic. They also noted the occasional presence of an evanescent primary lesion. These observations were amplified in 1922 by a pupil of theirs, Phylactos⁸. He pointed out that the disease was relatively common, was transferred by coitus, and had an incubation period of from ten to twenty-five days. He felt that it was an independent disease that should be differentiated from Hodgkin's disease, tuberculosis, syphilis, soft chancre and bubonic plague.

Pardo-Castello⁹ in Havana, Destefano and Vacca rezza¹⁰ in Argentina and de Bellard¹¹ in Venezuela have observed cases of this syndrome. In 1925, Frei¹² reported a skin test for the disease. Since then, as the specificity of this test has been proved and as the scope of the disease has widened, interest in the whole problem has greatly increased. The result is that there has been an enormous increase in the number of reports on the condition, almost entirely from Europe and South America. The first complete report in the United States was made by DeWolf and Van Cleave¹³ from our clinic in 1932. The reader is also referred to the complete monograph by Hellerstrom¹⁴ and to recent complete reviews of the entire subject by Hellerstrom¹⁵ by Koch¹⁶ and by Ravaut and Cachera¹⁷. A symposium on Nicolas, Durand and Favre's disease (lymphogranuloma inguinale) was held at the dermatologic clinic in Strasbourg in March, 1931, and reported in the bulletin of the French Dermatologic Society¹⁸.

As reports on the disease have increased, new names for the condition have multiplied. Nicolas, Durand and Favre suggested "subacute inguinal lymphogranulomatosis." Scheube named it "climatic bubo." It has also been given such names as "the fourth venereal disease,"

"tropical bubo," "maladie de Nicolas et Favre," "subacute inguinal paradenitis," "strumous bubo," "subacute inguinal lymphadenitis" and "nontuberculous granulomatous lymphadenitis." The term lymphogranuloma inguinale seems to be used most extensively in Europe, though it is an entirely separate condition from granuloma inguinale. Lymphogranuloma inguinale is a disease of the lymph channels and of the nodes, while granuloma inguinale involves the skin and subcutaneous tissue. Both diseases are, of course, generally spread by impure sexual contact. Nevertheless, current medical usage will probably continue the name lymphogranuloma inguinale.

CLINICAL SYMPTOMATOLOGY

After an incubation period varying from ten days to three weeks post coitus, the patient notes a swelling of the inguinal lymph nodes. This may be mild or quite severe. It may be unilateral or bilateral, and in probably 50 per cent of the cases it will be associated with generalized symptoms of chilliness, lassitude, pains in the joints and muscles, stiffness of the neck, and headaches. Occasionally, gastric symptoms are noted.

Fig. 1—Bilateral lymphogranuloma inguinale, showing a multiple fistulous opening.

Observation of the temperature may show it to be remittent, intermittent or even of the typhoid type, and it is not rare for a patient to enter the hospital with a temperature around 39 or 40 C (102.2-104 F). Occasionally the fever will persist for several weeks—probably as new nodes continue to be involved.

Local examination of the genitalia generally yields nothing, but in scattered instances either one will get a history of an evanescent lesion or actual objective symptoms will still be present. They seem to be of four types: (a) a fleeting herpetic lesion resembling a herpes praeputialis, (b) an ulcerative lesion, (c) a nodular lesion resembling somewhat a primary lesion, and (d) a specific urethritic type. These last cases, though presenting a discharge, show no gonococci. In women, it may be most difficult to find the primary port of entrance for the virus.

The time of the appearance of the genital lesion after exposure is difficult to determine definitely, as the primary lesion is often fleeting in type or never even noted. Probably a few days to a week or more would adequately cover this period. Generally, within from ten days to two or three weeks post coitus, the draining

lymph nodes will begin to enlarge. With a lesion of the male genitalia, this means the superficial inguinal nodes. At first the swelling will be more or less uniform, rather hard and tender. As time goes on, the nodes fuse to the skin, which takes on a reddish violet tint—the "adente violette" of Phylactos.⁶ The affected skin, being put on a stretch from the local enlargement, becomes quite shiny. Later, multiple areas of softening will appear and eventually the process breaks down with characteristic multiple fistulous openings as compared to the broken down chancroidal bubo in which is found a large single opening. As new nodes are involved, these also may go through the same cycle. The deep iliac lymph nodes in the pelvic fossa may secondarily become involved—a significant, almost pathognomonic sign—but they do not break down. As will be shown later, the inguinal localization of the disease in females is rare and the inguinal nodes are not so greatly affected. Owing to the lymph supply of the female genitalia, the process is more prone to spread to the deeper pelvic nodes and to the lymph nodes of Gerota around the lower part of the rectum.

Along with the local lymph node reaction, one occasionally finds a generalized lymph node enlargement, the spleen may be enlarged, the joints may be swollen, and even a general polyarthritis may be present. General skin manifestations, such as erythema nodosum and erythema multiforme-like eruptions, urticaria and scarlatiniform eruptions, have been noted by Hellerstrom,¹² Frei,¹¹ Klaue,¹⁷ Lohe and Blummers¹⁸ and others. Episcleritis has been seen by Guttentag,¹⁹ and three such cases have been observed in our own clinic. Pustular elements on the skin in connection with the disease have been seen by Chevallier and Bernard²⁰ accompanying an erythema nodosum and arthralgia of the knees.

The disease as seen in the female may take on quite a different aspect. In fact, it is suspected by more than one investigator that the female may sometimes harbor the infection as a saprophyte. Thus, Schulmann²¹ reports a case of lymphogranuloma inguinale in a young student. Examination of the student's paramour revealed a banal metritis and some painless, movable inguinal lymph nodes. Sezary, in discussing the case, said that he had seen a woman with a positive Frei reaction and no symptoms, while her husband had a typical lymphogranuloma inguinale.

This is not the case in all females, however. In some of them one may even find a fleeting primary lesion of one of the four types described. Moreover, rarely the inguinal nodes may go through the same gamut of reactions as in the male. A careful review of studies on the lymph supply of the male and female genitalia has been made by Barthels and Biberstein²² and by Jersild.²³ These writers show that the lymph nodal reactions of the disease are dependent on the draining lymph supply to the parts. In the male, most of the lymph channels of the genitalia drain into the inguinal and secondarily into the deeper iliac nodes. Therefore, these nodes are the ones most often affected. In the female, on the

contrary, only the lymph from the clitoris and external vulva drains into the inguinal nodes, while the supply from the vaginal mucosa, and especially from the posterior vaginal wall, drains into the lymph nodes around the rectum, where there are three lymph plexuses extending together up in the rectum to a height of from 4 to 6 cm. Consequently, if this is true, one would

Fig 2—Extensive fistulous esthiomene of years' duration showing perianal fistulous opening. The Frei reaction was positive.

rather look for symptoms in the female to be located more in the nodes of the lower part of the rectum and of the floor of the pelvis. Is this true in actual practice?

"ANORECTAL SYNDROME"

As long ago as 1848, Huguier²⁴ described a condition of the vulva in which there was an elephantiasis of the tissues and an accompanying chronic, progressive ulceration, involving the labia, the perineal body, the anal orifice and often the lower part of the rectum. The author described a superficial, a perforating, a hypertrophic and a mixed type. Lesions were most often situated over the posterior commissure and over the perineal body. Very often there was an accompanying stricture of the rectum—Bandelier says it always accompanies the trouble. Huguier felt that it was due to tuberculosis, and Larsen²⁵ of Copenhagen, in 1849, thought it was due to syphilis.

In 1875 the French syphilologist Alfred Fournier described a syndrome he had observed consisting of perineal and rectal multiple fistulas. He also noted the fact that the rectal wall was infiltrated and narrowed. Fournier thought the trouble was due to syphilis and it has been known in medical literature as the "anorectal syphiloma of Fournier." Audry and Puechar²⁶ give the first description of elephantiasis of the vulva accompanying the "syphiloma"; they thought it was due to lymph stasis. Fournier later confirmed the coexistence

of the "anorectal syphiloma" and of chronic vulvar lesions. The rectal condition was most often seen in the female, and he spoke of its being rebellious to treatment. A like chronic elephantiasis of the male genitalia has been described by Barthels and Biberstein²² in which a study of the tissue showed it to be the histologic picture of lymphogranuloma inguinale. There was obstruction of the lymph channels with the specific growth.

Various explanations have been offered for esthiomene, including lack of cleanliness, banal ulceration and gradual spread because of its location and chances of reinfection, prostitution, chronic chancroidal infection, gonorrhea, and chronic lymphangitis following a local infection.

For years, Jersild²³ of Copenhagen has been interested in this problem. As far back as 1920 he was convinced that the "anorectal syphiloma" of Fournier was not syphilitic but an elephantiasis of the tissues due to lymph stasis—through obliteration of the inguinal and rectal lymph nodes. He thought that a chronic chancroidal infection was the cause of the trouble and that the "anorectal syphiloma" of Fournier was identical with the esthiomene of Huguier or with the condition described by Jadassohn as "ulcus vulvae chronicum elephantasticum." Darier had already termed this elephantiasis as the "pendant" to the syphiloma of Fournier. The fact that made Jersild suspicious of the syphilitic cause of the trouble was that in several of

Fig 3—Chronic perianal nodules and scar formation accompanying a high grade stricture of the rectum. The Frei reaction was positive; the Wassermann reaction negative.

the so-called anorectal syphilomas the patient later developed an early syphilis which could not be attributed to reinfection. Moreover, about this time, 1925 the specific skin reaction for lymphogranuloma inguinale, as worked out by Frei and the specific skin reaction for chancroid, as worked out by Ito-Reenstierna, were reported. Jersild reported that the Frei reaction was positive and the Ito-Reenstierna and Wassermann reac-

²⁶ Audry and Puechar, cited by Jersild.²³

tions were negative in certain of his earlier studied cases. He also reported a woman with a typical esthromene of fourteen years' duration in which the Frei reaction was positive and the chancroid and Wassermann reactions were negative. He now is convinced that the rectal lesions in the so-called anorectal syphiloma of Fournier are secondary to an adenopathy of the ganglion of Gerota, surrounding the lower part of the rectum, and that they are not chancroidal but rather lymphogranuloma inguinale.

Barthels and Biberstein, following the report of Frei and Koppel,²⁷ have made a very careful study of the inflammatory rectal strictures. Most of these strictures appear in females. They involve the lower 9 to 10 cm. of the rectum and, in fact, most of them do not extend higher than 6 cm. The tendency of the infection of the rectal and pelvic lymph nodes in the female is to an inflammation which spreads to the rectal walls through the lymph channels. Later lymph thromboses take place. The end-result is inflammation and scar formation with narrowing of the rectal lumen. The stricture may be bandlike or, if all the lymph plexuses are involved, tubular in character. The authors reported five cases, all with a positive Frei and a negative Wassermann reaction. One of their patients had an elephantiasis of the vulva and ulceration of the posterior commissure. In four cases, the rectal mucosa was cornified and in three there were extensive ulcers above the anus. In cases 2, 4 and 5 the rectum and vagina were closely bound together by scars, and in case 4 amputation of the lower rectum was impossible.

Bensaude and Lambling²⁸ have reported an extensive study of forty-eight cases and confirm the observations of Barthels and Biberstein.

Fig. 4—Characteristic bilateral lymphogranuloma inguinale. Three Frei reactions on the right forearm still positive after ten days.

As already mentioned, the male ordinarily does not get this grave complication because of the lymph supply to the genitalia draining first into the inguinal and iliac nodes. Occasionally this does take place however. In a homosexual person one would expect the local

process in the rectum, as in the case reported by Ravaut and Levaditi.²⁹

To sum up the present feeling in regard to the cause of the inflammatory stricture of the rectum and its relation to lymphogranuloma inguinale, Seneque³⁰ says there are four forms: (a) a pure stricture limited to the rectum, (b) a rectal stricture with elephantiasis of

Fig. 5—Anorectal syndrome with rectal stricture and cauliflower-like perianal lesions in a male. The Frei reaction was positive.

the external parts, (c) rectal stricture complicated with fistulas and in the past classified as tuberculosis because it is granulomatous in character, even though Koch's bacillus is not found, and (d) rectal stricture with pelvic cellulitis.

ETIOLOGY

It was suspected for some years that lymphogranuloma inguinale was due to an organism as most of the cases followed venereal exposure. Moreover, so-called conjugal cases had been reported by Mamou,³¹ Chevalier and Bernard,³² Gate, Michel and Morel,³³ and Lepinay and Grevin.³⁴ Nicholas³⁵ reported the cases of three soldiers exposed to the same female, all of whom contracted lymphogranuloma inguinale, moreover, one of the soldiers was married and his wife likewise later came down with this disease. Several cases of the disease have been observed in physicians from extragenital infection, the most celebrated being that reported by Hellerstrom. The physician was infected on the finger in the autumn of 1904 while operating on a patient with inguinal adenitis of unknown origin. His axillary nodes later went through the typical course of lymphogranuloma inguinale and required extirpation, eventually healing. Years later,

in 1927, Hellerstrom did a Frei reaction on the patient and found it to be positive. Buschke³⁶ has also reported an involvement of the submaxillary nodes from a lesion of the tongue following unusual sexual relations.

Naturally, numerous attempts have been made to find the cause of the disease and a variety of organisms have been reported but not confirmed by later studies. Hellerstrom and Wassen³⁷ were finally able to report at the eighth International Dermatologic Congress in Copenhagen in 1930 the successful subdural transmission to apes. This work has since been confirmed by Levaditi and Ravaut and their associates³⁸. Moreover, Levaditi, Marie and Lepine³⁹ have, after several passages through apes, again successfully transmitted the disease to human paralytic patients through preputial inoculations. The lymph nodal changes produced in these cases corresponded with the typical disease as seen in man. The disease as seen in the apes has the characteristics of an encephalitis which becomes more fatal³⁸ and has a shorter incubation period as it adapts itself to the host. It is a filtrable virus⁴⁰. The virus loses its virulence very rapidly in glycerin but holds its virulence in the frozen state at least twenty-two days⁴¹. Apes inoculated subdurally also have the virus in the liver, spleen, kidneys, cord and lymphatics. The virus does not penetrate a collodion sac⁴² but is transmissible to white mice⁴³. Working with human beings (patients with dementia paralytica), Chevalier and Bernard⁴⁴ have found that inoculations depend on the virulence of the virus and also on the host. Certain strains are quite virulent, and in others symptoms are hardly apparent. Successful transference to guinea-pigs⁴⁵ and rabbits has been reported. The latter resulted in a histologic and biologic meningo-encephalitis for it could be further transmitted to lymph nodes of rabbits and guinea-pigs. Meyer and Anders⁴⁶ also claim to have successfully grown material which they could transfer to guinea-pigs.

PATHOLOGY

If one removes surgically a mass of lymphogranuloma inguinale lymph nodes grossly there is a dense perinodal exudation binding the nodes together. These nodes on section, show multiple whitish areas of softening abscesses. If the nodes are in an early stage, they may simply show reddening. The histologic picture has been carefully described by Nicols and Favre, Hellerstrom, DeWolf and Van Cleve and others. It resembles somewhat the appearance of tuberculosis—certainly of a granuloma. One finds specific granulation tissue with areas of necrosis walled off by phasades of epithelioid cells. These areas of necrosis often assume a starlike shape, often there is an extensive impouring of leuko-

cytes. It probably is not always possible to differentiate the picture from a tuberculosis,⁴⁷ or from a syphilitic or other infectious lymph node state⁴⁸. The abscesses in the glands nearly always show much broken down material, and giant cells may be found in different portions of the nodes.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

Given a patient who has an inguinal adenitis following a transitory genital lesion the possibility of lymphogranuloma inguinale must always be kept in mind. The large mass of prominent nodes sooner or later fixing themselves to the skin, which takes on a violaceous tint, is very characteristic of this disease. Miskjian⁴⁹ suggested the descriptive term "hypertrophic bubo". The diseases to be most frequently differentiated from lymphogranuloma inguinale are lymph nodal reactions in connection with chancroids and with syphilis. Granuloma inguinale is a disease of the skin and not of the lymphatic system so it will not have to be seriously considered. The lymph nodal reaction in chancroids is more that of an acute painful adenitis which softens and breaks down with one central area of necrosis. The typical picture in lymphogranuloma inguinale on the other hand, is that of multiple areas of suppuration, corresponding to the multiple abscesses in the nodes. In a case of chancroids, the bacillus of Ducey will be found in smears made from local lesions on the genitalia. Finally, in a case of chancroids gone on to the stage of adenitis, the patient will have a positive Ito-Reensterna⁴⁹ reaction. This is a specific intradermal test corresponding to the tuberculin test, carried out by the injection of killed bacillus of Ducey organisms.

In syphilis, the lymph nodal reaction is that of a sharply defined hard, painless set of nodes which do not break down unless complicated with some other disease. Moreover, there would ordinarily be evidence of a primary lesion, and the dark field illuminator and the Wassermann test would go far to settle the diagnosis.

Other conditions that at times may enter into the picture are Hodgkin's disease, tuberculosis, the bubonic plague, tularemia malignant growth and possibly a pyogenic infection.

The diagnosis of lymphogranuloma inguinale has been greatly aided by the report of Frei,⁵¹ in 1925, of a specific intradermal test. A suppurating lymph node not yet opened in a person having lymphogranuloma inguinale but who has never had a chancroidal infection or syphilis, furnishes the material for the test. Pus from this node is removed aseptically through a small incision, either by using a large bore needle or through introducing the tip of a record syringe and aspirating it. The material is diluted 1:4 or 5:10 depending on its thickness with sterile salt solution. It is sterilized at 60 C for two hours one day and 60 C one hour the succeeding day. Afterward it is tested for sterility and put up in ampules. The antigen is then tested on known cases of lymphogranuloma inguinale, of course the antigen from the source patient must not be tested on the same patient. In known cases of this disease it should give a positive reaction, and in normal persons and in cases of chancroid a negative reaction. For the test which corresponds to the tuberculin test an intradermal (not subcutaneous) injection of 0.1 cc is

made and the reaction is read in forty-eight hours. If the test is positive, it will show a red papule at least 0.5 cm in diameter. It may show a large erythematous halo around it, or it may even be so positive as to go on to necrosis. One negative test is not sufficient to rule out a lymphogranuloma inguinale. Some investigators claim that the test will not become positive until the lymph node has fused with the skin. Generally it will be positive within from ten days to two or three weeks after the adenitis is evident, and, as a rule, the positive state persists, probably throughout life. In other words, the patient develops an allergic state and probably such an individual cannot again acquire the disease, though this is not as yet entirely confirmed. In Hellerstrom's case, a positive reaction still showed after twenty-three years, and recently in our clinic there was observed a patient with a positive reaction after thirty years.²⁰ The reaction is specific for this disease only. The antigen used will ordinarily keep its potency for six months or even up to one year. One must be careful not to work with an antigen secondarily infected, for a false positive will result. In using an antigen, it is well to employ at least two others with it as controls. If the patient with the lymphogranuloma inguinale has a concomitant fresh syphilis, the Frei reaction may be masked (anergy) for the time being until the syphilis is under partial control. Any disease causing a breaking down of the patient's allergic powers may cause a temporary negative Frei reaction in an otherwise positive case. The Frei reaction has been of particular value in the diagnosis of the so-called anorectal syphiloma of Fournier and the anorectal syndrome of Iersild with elephantiasis of the vulva. In cases of chronic ulcerative elephantiasis ulcerations of the vulva going under the term *esthiomene*, a Frei reaction is most valuable, though certain of these cases with prolonged illness and lessened general resistance may show an anergy and should not, on the strength of a single negative reaction, be considered as not due to lymphogranuloma inguinale.

Much interest has arisen from the fact that antigens prepared from the brains of infected monkeys²¹ give the same specific Frei reaction as with human materials when used on human beings. It has been suggested that, in a suspicious case under study, if the diagnosis cannot be made otherwise, some lymph node material be taken from the patient, an antigen prepared, and this antigen tried out in known cases of lymphogranuloma inguinale.

It probably should be mentioned that fresh cases of lymphogranuloma inguinale for a period of time during the acute stage of the disease occasionally will give false positive Wassermann reactions.²² This is a very important finding, as a 3 plus Wassermann reaction in a patient with inguinal adenopathy might easily be mistaken for syphilis and treatment instituted. Given such an exceptional case in which no other evidence of syphilis can be found, further Wassermann reactions and Frei reactions should be tried before the case is finally diagnosed as syphilis. We are convinced that, in the past, quite a few such cases have, on the strength of a glandular reaction following sexual exposure, been diagnosed as syphilitic because of a fleeting false positive reaction and treatment for syphilis has been instituted.

REPORT FROM THE CLEVELAND CITY HOSPITAL AND WESTERN RESERVE CLINIC

Since the report of DeWolf and Van Cleave was made from our clinic, March 15, 1932, fifty-two additional cases have been observed up to April 26, 1933. It well illustrates the fact that this disease is not an uncommon one in general city hospitals in the United States. In fact, with sufficient care in differential diagnosis, probably as high a proportion of these patients will be found in other clinics in this country.

POSITIVE FREI REACTIONS SYMPTOMS OF THE DISEASE ABSENT

Naturally, the Frei test has been used quite widely in our hospital, especially on patients with rather suspicious histories or symptoms. Twenty-two positive reactions have been picked up, all but one in male patients having histories of buboes running back from six months to between thirty and forty years. In five of these cases there was no definite time history as to the bubo. There was a history with one patient of a bubo two years before, with two, three years before, with two, five years before, with three, from ten to fifteen years before, with three, from fifteen to twenty years before, with two, from twenty to twenty-five years before, with two, thirty years before, and with one, between thirty and forty years before. Of the two patients with histories of buboes thirty years before, one had been treated at the Lakeside Hospital for what was then called a gonorrheal adenitis. The glands had been removed surgically. Pathologic diagnosis on the glands was that of an acute purulent inguinal adenitis. No gonorrheal organisms were found. In one additional case there was a fluctuating Frei reaction with no history of a bubo, but there had been a urethral discharge nine months previously. Otherwise, no positive Frei reactions were found except either in patients giving histories of buboes or in patients showing scars in their groins.

ACUTE LYMPHOGRANULOMA INGUINALE

We have encountered thirty-six male cases and one female case of early bubo forming lymphogranuloma inguinale in the same period of time. There were twenty-two Negro and fifteen white patients. The incubation period varied from two or three days up to several weeks before symptoms appeared. Sixteen of the patients had primary lesions, three of them being on the order of the urethritis type, which might be easily confused with a gonorrhea. Five of them showed small ulcers, two of them being just inside the urethral orifice. Seven had a small papular primary lesion. Gonorrhea was not found in connection with patients with a urethral discharge. In almost one half of the patients there was fever, either remittent or intermittent in type, occasionally quite severe—even up to 40 C (104 F) and accompanied with chills and night sweats.

Conjunctivitis was noted in three cases, arthritis was a severe symptom three times, and an erythema nodosum-like eruption of the body was seen once and an erythema multiforme-like eruption also once. The bubo was unilateral in twenty-one cases, bilateral in thirteen, and not noted in five cases. Needless to say, the Frei reaction was positive in every case, and the earliest reaction was eighteen days following the intercourse and four days after the appearance of symptoms of the bubo.

ESTHIOMENE AND THE ANORECTAL SYNDROME

Material showing symptoms of anorectal involvement and of ulcerative elephantiasis of the vulva, esthiomene, seen in the last year, comprised fifteen cases—thirteen females and two males. There were one white and one Negro male and eleven Negro and two white females. All the patients showed positive Frei reactions and seven of them had negative Wassermann reactions, though in the latter patients there was one with an old syphilis.

There were two examples of esthiomene, both in Negro patients, one patient had numerous deep dissecting fistulas through which probes could be passed for a long distance and which even connected up with the rectum. This patient was syphilitic but did not respond to antisyphilitic therapy. The other patient had a concomitant annular stricture 3 cm above the rectum. She showed moist fungoid masses in the lower margins of the vulva. Microscopic examination of the tissue showed fibrous tissue formation with lymphocytic infiltration. Foci of plasma cells and eosinophils were noted, also several areas of necrosis surrounded by large endothelial cells and some granuloma-like giant cells. There was a moderate vascularity.

One of the male patients had numerous anal excrescences, some elephantiasis of the scrotum and concomitant annular stricture of the rectum. The other male patient complained of obstinate constipation of seven years' duration. He had been treated at the Cleveland City Hospital for a bubo fifteen years previously. He had an annular stricture about 6 cm up the rectum and proctoscopic examination showed white fibrous scar tissue extending down from the ring stricture to the anal orifice.

Several of the female patients showed an anorectal syndrome with cauliflower-like indurated lesions around the anal orifice and attendant stricture of the rectal wall.

Most of the strictures were annular in type, though five of them were more diffuse and were tubular in character, in one instance extending 10 cm up from the anal orifice. Biopsy made from one of the strictures was reported to show simply chronic inflammation. Proctoscopic examination in one case showed "an acute and chronic ulcerative process with small elevated red islands, there was fibrosis of the posterior rectal wall."

In two instances there was an induration of the entire pelvic floor, and in neither case was the Wassermann reaction positive. In still another case there was reported to be a mass in the posterior vaginal wall. In one woman colostomy and repeated transfusions were found necessary to save her life, and in another patient with a stricture too small to allow passage of a pencil, operation was refused and the patient went home to die.

TREATMENT

The results of therapy in lymphogranuloma inguinale vary. Klotz² as far back as 1890 stated that he had had good results from total extirpation of the lymph nodes. This view has been shared in part by others. The case in our clinic, in which such an operation was performed thirty years ago by Dr. Henry L. Sanford, resulted in cure of the disease; it is true but the patient has had a brawny elephantiasis extending down to the shoe top ever since. Willoughby⁵² deplores even opening the nodes as they then suppurate for a long time.

On the other hand, Danel⁵³ simply removed a small node for biopsy in a case of lymphogranuloma inguinale, the patient returned two and one-half months later improved and in another month was well. Nicolau⁵⁴ and Barthels and Biberstein agree with Frei that partial removal of the suppurating nodes gives good results. Total extirpation, on the other hand, leads to a troublesome elephantiasis. Even if the nodes show evidence of receding without therapy, they think it well to open at least one area and allow drainage. Otherwise, in their opinion, there is possible danger of further spread to other nodes and perhaps more serious consequences, for example, anal stricture. The multiplicity of remedies suggested is probably good evidence of the inconclusive effect of various therapeutic agents thus far tried. Potassium iodide internally has been suggested; the intraglandular injection of 2 cc of glycerin into the open bubo once a week has been recommended by Pinard and Andre⁵⁵ and others. Foreign protein therapy of various types has been tried. In some instances it seems to be helpful. In our clinic some years ago Miskin⁵⁶ tried out the old fashioned seton, employing a strand of catgut through the node and tying the two ends on the outside. It promoted free suppuration and discharge and gave good results. This, in a way, would correspond to the suggestion of Barthels and Biberstein. Destefano and Vaccarezza are great believers in the use of intravenous injections of solution of antimony and potassium tartrate, and in our hands this therapy really has given benefit. Nicolau⁵⁴ has suggested 10 cc of compound solution of iodine intravenously every second day. Emetine has also been tried, as well as salts of iron, of copper, of arsenic and of mercury. High voltage roentgen therapy⁵⁷ has been tried in several clinics. Our own results have not been so happy, and Nicolas and Favre have noted that fistulas heal badly with this therapy. Gay-Prieto,⁵⁸ Levaditi and Ravaut, and Hellerstrom have had some beneficial action from the intravenous use of the Frei antigen strained through gauze, employing increasing doses of from 0.2 to 2 cc. In my estimation, rest in bed, promotion of free drainage, perhaps along with partial extirpation of the nodes involved, and the use of solution of antimony and potassium tartrate intravenously gives the best results. Naturally, the results in none of the cases of esthiomene and of anal stricture are particularly good.

SUMMARY

1 Lymphogranuloma inguinale is a distinct granulomatous entity involving the lymph nodes and is generally venereal in origin. After an incubation period of from one to several weeks, and not necessarily accompanied by a primary sore, there results a chronic bubo formation which eventually goes on to suppuration.

2 In the female and rarely in the male, the lymph nodes around the lower portion of the rectum may be involved, the inflammatory reaction often resulting in strictures of the rectum. Occasionally, in the female there may be involvement of the lower vaginal wall and labia in the form of a chronic ulcerative elephantiasis—esthiomene.

3 The cause of lymphogranuloma inguinale is a filtrable virus which can be transferred to several of the

lower animals (monkeys, rabbits, white mice, guinea-pigs)

4 A specific diagnostic cutaneous reaction (Frei reaction) has been evolved, the emulsion material from unbroken involved nodes being used as the antigen

5 A series of positive Frei reactions were made in patients suspected of having had the disease in the past. Among them were two with histories of buboes thirty years before, and one with a history of bubo between thirty and forty years before. This allergy of the skin apparently persists through life. Thirty-seven cases of lymphogranuloma inguinale with bubo formation, as well as two cases of esthiomene and thirteen of anorectal symptoms with stricture of the rectal wall gave positive Frei reactions and many showed no history or signs of syphilis or tuberculosis

6 Patients with bubo formation seen early responded comparatively well to surgical excision of the involved nodes or to the use of intravenous injections of solution of antimony and potassium tartarate

7 This study leads me to believe that this disease is by no means a rare disease in America as this material was noted in one clinic in the course of a year's study

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

AUTOLYZED LIVER CONCENTRATE-SQUIBB

—A mixture containing autolyzed liver concentrate 88 per cent and cocoa 12 per cent. Each gram is derived from approximately 7 Gm of fresh liver and represents the antianemic potency of from 20 to 30 Gm of fresh mammalian liver.

Actions and Uses—Autolyzed liver concentrate Squibb supplies the antianemic potency of liver in a form that is palatable and convenient. The product is also rich in vitamin B₁ and G.

Dosage—Four to six or more teaspoonfuls in divided doses daily for a period of ten days thereafter a maintenance dose of one to two teaspoonfuls daily is usually sufficient.

Manufactured by E. R. Squibb & Sons, New York, by license of the University of Pittsburgh Medical School. U. S. patent applied for. No U. S. trademark.

Fresh edible livers which have been chilled immediately on removal from the body are ground and mixed with fiftyth normal hydrochloric acid. Sufficient chloroform is added to act as a preservative and prevent bacterial growth. The mixture is incubated at 37° C. and autolysis allowed to proceed from five to ten days. The solution is then filtered to remove any undigested material; the filtrate which contains the active material is desiccated at a lower temperature in vacuo and the resulting mass ground to a fine powder. Twelve per cent cocoa is added as flavoring. Each gram of the finished product represents the antianemic potency of from 20 to 30 Gm of fresh mammalian liver.

POLLEN ALLERGEN SOLUTIONS-SQUIBB (See New and Nonofficial Remedies, 1933 p. 30)

The following additional products marketed in 5 cc vials containing 10,000 protein nitrogen units per cubic centimeter have been accepted:

False Ragweed Combined Pollen Allergen Solution Squibb (False Ragweed and Slender Ragweed in equal parts) *Orachs (Shadscale) Pollen Allergen Solution Squibb (Shadscale Redscale and Hinescale in equal parts)* *Oregon Ash Pollen Allergen Solution Squibb (Ragweed Combined Pollen Allergen Solution Squibb (Giant Ragweed and Dwarf Ragweed in equal parts)* *Rye Grasses Combined Pollen Allergen Solution Squibb (Perennial Rye Grass and Italian Rye Grass in equal parts)* *Sagebrush Combined Pollen Allergen Solution Squibb (Sagebrush and Pasture Sage in equal parts)* *Wormwoods Combined Pollen Allergen Solution Squibb (Biennial Wormwood Dragon Sage-wort Dark leaved Mugwort and Mugwort in equal parts)*

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND O. HERTWIG, Secretary

JUNKET TABLETS (NOT SWEETENED OR FLAVORED) JUNKET POWDER (WITH SUGAR AND FLAVOR) VANILLA, CHOCOLATE, LEMON, ORANGE, RASPBERRY AND COFFEE FLAVORS

Manufacturer—Chr. Hansen's Laboratory, Inc., Little Falls, N. Y.

Description—Junket Tablets: rennin tablets containing salt starch, calcium phosphate and rennin.

Junket Powder: rennin powder containing sucrose, flavor, calcium glycerophosphate, gum tragacanth or gum arabic. The flavors are respectively vanilla, orange and lemon oils, raspberry and coffee extracts, and cocoa. The orange, lemon and raspberry flavored powders are artificially colored with United States Department of Agriculture certified colors, and the coffee flavored powder with caramel color.

Manufacture—Calves' stomachs (rennets) of tested milk coagulating strength from government inspected newly killed young milk fed calves are trimmed of fat and are either salted or blown up and dried. 'Green flat salted rennets' are prepared by slitting and stretching the stomachs out flat; they are piled with intervening layers of salt and allowed to drain; which treatment shrinks the fiber, whitens the rennets and dries them out for handling. 'Dried flat salted rennets' are prepared by drying salted rennets on racks at below 39° C. 'Blown and dried rennets' are prepared by drying blown up rennets below 39° C.

The 'flat salted' and 'dried blown' rennets are machine shredded, extracted with 10 per cent brine containing 0.2 per cent chloroform in refrigerated rooms; the brine extract is drawn off and is saturated with sodium chloride to precipitate the rennin, which is separated out and pressed to remove free liquid. The 'press cake' is mixed with salt and dried in warm air; the resulting powder is used for making Junket Tablets. The 'press cake' admixed with milk sugar is used for Junket Powder.

The variously flavored Junket Powders are prepared by mixing the rennin powder and cane sugar with small amounts of calcium glycerophosphate with the respective flavoring ingredients. Definite quantities of the mixes are packed in packages such that one package will coagulate one pint of milk at 43° C. in from three to five minutes.

Analyses (submitted by manufacturer) —

	Tablets	Vanilla Flavor	Orange or Lemon Flavor	Rasp. berry Flavor	Coffee Flavor	Chocolate Flavor
Moisture	0.0%	0.2%	0.2%	0.2%	0.3%	0.8%
Ash		0.5	0.5	0.2	0.6	1.1

Caffeine					0.04	0.06
Theobromine						0.25
Starch	0.6					
Calcium phosphate	1.0					

Calories—Junket powder approximately 4 per gram, 114 per ounce.

Claims of Manufacturer—For preparing plain 'junket' or junket with various flavors. A tablet or a package contains sufficient rennin to coagulate one pint of fresh or pasteurized milk in three minutes at 43° C. Finished dessert made from

one package of Junket Powder and one pint of milk provides about 500 calories (four servings) for the chocolate flavored powder about 560 calories. The active ingredient rennin transforms milk into eustard-like milk-food or dessert.

Junket Tablets (not sweetened or flavored) For making milk-foods for invalids and children. Junket desserts, ice cream and cheese, also for preparing milk for infant feeding and special diets.

Junket Powder (sweetened and flavored) requires milk only for making flavored and sweetened milk desserts, ice cream, etc.

MCCORMICK'S BEE BRAND BLACK PEPPER MCCORMICK'S BEE BRAND WHOLE BLACK PEPPER

Manufacturer—McCormick and Company, Inc., Baltimore

Description—Whole or ground black pepper (berry of *Piper nigrum* L.)

Manufacture—The black pepper is the dried fruit of a perennial climbing shrub. The berries are picked before fully ripe, sun dried on mats or over slow burning fires during which time they shrivel and become dark brown or black, are freed from twigs, leaves and foreign material and are exported to the company's packing plant, cleaned, ground and packed in tins.

Analysis (submitted by manufacturer) —

Claims of Manufacturer—Conforms with the respective United States Department of Agriculture definition and standard.

HIGH GRADE QUALITY A FLOUR (BLEACHED)

Manufacturer—Federal Mill Inc., Lockport, N. Y.

Description—A 'patent' hard winter wheat flour, bleached.

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one fourteenth ounce per 196 pounds) and nitrogen peroxide.

Claims of Manufacturer—Intended for bread baking.

CLAPPS ORIGINAL LIVER SOUP

(LIVER, VEGETABLES, CEREAL, MEAT BROTH AND SALT)

Manufacturer—Harold H. Clapp, Inc., Rochester, N. Y.

Description—Strained cooked soup stock prepared from calf's liver, potatoes, tomatoes, carrots, unpolished rice, cabbage, celery, meat broth, whole grain barley, salt, onions and water. The method of preparation is efficient for retention in high degree of the natural vitamins and minerals.

Manufacture—Government inspected calf's liver is chopped fine and strained raw. The liver and Clapps' Original Baby Soup are mixed in definite proportions, cooked, strained, jarred, capped and processed as described for Clapps' Original Baby Soup (THE JOURNAL, June 24, 1933, p. 2011).

DOLE VACUUM PACKED HAWAIIAN FINEST QUALITY PINEAPPLE (SLICED, CRUSHED, TIDBITS AND HALF SLICES)

CORAL SEA, DISCOVERY, MAUNA LOA, PALM ISLAND PARADISE, RECIPE SWEET TREAT AND TREASURE ISLAND BRANDS

Packer—Hawanan Pineapple Company, Ltd., San Francisco.

Description—Canned pineapple (slices, half slices, crushed and tidbits) packed in concentrated pineapple juice syrup with added sucrose. The same as Doles 1, 2 and 3. Hawanan canned pineapple products (THE JOURNAL, April 8, 1933, p. 1106 and April 29, 1933, p. 1338).

CLAPP'S ORIGINAL PUREE OF SPINACH (ADDED SALT)

Manufacturer—Harold H. Clapp, Inc., Rochester, N. Y.

Description—Strained cooked spinach, a small amount of salt is added. The method of preparation is efficient for retention in high degree of the natural vitamins and minerals.

Manufacture—Purchased canned spinach is strained in an atmosphere of water vapor and subsequently treated as described for Clapps' Original Baby Soup (THE JOURNAL, June 24, 1933, p. 2011).

The purchased canned spinach is prepared from spinach inspected to remove unsuitable material, sorted, passed through a washing reel, blanched with steam, again inspected, packed in cans with a salt solution and passed through a hot water exhauster to bring to 71°C and remove absorbed air. The cans are sealed, processed at 116°C for 100 minutes and immediately cooled.

Vitamins and Claims of Manufacturer—See Clapps' Original Baby Soup (THE JOURNAL, June 24, 1933, p. 2011).

HOLSUM TWIN LOAF SPLIT LOAF HOLSUM BREAD LONG LOAF

Manufacturer—The Holsum Baking Company, Morgantown, W. Va.

Description—White bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817) prepared from patent flour, water, dextrose, powdered skim milk, lard, yeast, salt, malt extract and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride, potassium bromate and corn starch.

SCOUT CABIN BRAND EVAPORATED MILK

Packer—Amboy Milk Products Company, Amboy, Ill.

Distributor—E. Bierhaus & Sons, Vincennes, Ind.

Description—Canned unsweetened evaporated milk, the same as Amboy Brand Unsweetened Evaporated Milk (THE JOURNAL, May 7, 1932, p. 1655).

POLAR BLAR FLOUR

Manufacturer—The New Era Milling Company, Arkansas City, Kan.

Description—An all purpose hard winter wheat patent flour.

Manufacture—Selected hard winter wheat is cleaned, scoured, washed, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one twentieth ounce per 196 pounds).

Claims of Manufacturer—Intended for all baking purposes.

THEORIES OF MUSCULAR CONTRACTION

In view of the importance of movement, the physiologist is intensely interested in the nature of the contractile processes in muscle by which so much of the body's activity is maintained. Even during the periods of utmost quiescence when the body seems to be entirely at rest, the contractions of the heart and of the muscles concerned with respiration never cease. An understanding of the way in which energy is transformed for the muscular functions is therefore of fundamental significance. Years ago the analogy of the combustion engine, in which the oxidation of fuel was a conspicuous feature, seemed to serve the purposes of explanation. The muscles were the organs in which food fuel of a suitable sort was somewhat mysteriously burned to produce movement. Incidentally there came the discovery of the development of acids other than carbonic acid incident to the contractile process. Lactic and phosphoric acids found their way into the picture, and they were for a time dismissed as the "fatigue products" of muscle, with all the uncertainty bred of inadequate knowledge. Somehow they did not fit into any simple theory of oxidative action as a basis of muscular work, although lactic acid in particular always seemed to make its appearance in the tissues in unusual amounts when muscles were made to contract.

Presently the more intensive studies in this field led to conceptions somewhat comparable to the changes in a "chemical engine." They culminated in the so-called Hill-Meyerhof theory of muscular contraction, gaining for each of the scientists named a Nobel prize. The resulting hypothesis, based on the myothermic studies of Hill¹ and the chemical investigations of Meyerhof,² is formulated in the textbooks of the present day. According to a recent summary,³ the primary change in muscular contraction is the anaerobic breakdown of

glycogen to lactic acid, followed by oxidative recovery, during which the major part of the lactic acid is resynthesized to glycogen by the energy derived from the oxidation of the smaller part to carbon dioxide and water. The discovery of phosphocreatine by Fiske and Subbarow was followed by their hypothesis that the base liberated by the hydrolysis of this substance buffers the muscle against the lactic acid formed during contraction.

This generalization has recognized certain facts of experimental observation but it has never been accepted with universal acclaim by actual workers in the field of muscle biochemistry. One of the disconcerting aspects arose when, as the situation has been stated by Jacob and Wilma C. Sacks,⁴ Lundsgaard⁴ in 1930 found that muscles poisoned with iodo-acetic acid could perform a certain amount of work without the formation of any lactic acid, and that the phosphocreatine in these muscles was completely broken down during activity. This discovery obviously invalidated the hypothesis that the formation of lactic acid was the sine qua non of muscular activity and put the emphasis on the breakdown of phosphocreatine as the energy-yielding reaction. Lundsgaard proposed and Meyerhof and Hill accepted this hypothesis. The primary chemical change in muscle contraction is the (hydrolytic) breakdown of phosphocreatine, the recovery process, which may be oxidative or anaerobic, is the resynthesis of this phosphocreatine, the energy for the anaerobic resynthesis is furnished by the formation of lactic acid from glycogen.

Experimentation on contraction calls for resourcefulness. When a muscle is investigated apart from the body, its supply of oxygen and the normal removal of products of chemical change are interfered with. The chemical changes may be minute and therefore require new and delicate analytic procedures to measure them with adequate precision. Many possibilities, including the more recently recognized phosphocreatine, adenine phosphate and hexosephosphates, along with oxygen, carbon dioxide, phosphoric acid and lactic acid, have called for consideration. Amid a wealth of facts there has been a tendency to welter in assumptions.

One by one, modifications have been introduced into the original Hill-Meyerhof formulations. There is little justification to recount the details here except as some real novelty is presented. This seems to apply to conclusions based on recent investigations in the Pharmacology Laboratory of the University of Michigan Medical School at Ann Arbor.³ The theory of the essential chemical changes involved in the contraction of muscle is presented as follows. The fundamental process by which chemical energy is converted into muscular work is an oxidative, not an anaerobic, one. The substance oxidized is derived from glycogen, presumably it is lactic acid, which is formed in small amounts necessary to maintain a relatively constant

supply During the initial stages of extreme exertion, before the circulation has had time to adjust itself, certain secondary anaerobic processes are employed to furnish part of the energy for contraction. These secondary reactions are the formation of lactic acid from glycogen in massive quantity and the formation of hexosephosphate from glycogen and phosphocreatine. The first of these is the reaction which Hill and Meyerhof formerly considered to be the primary change. The second is a statement of the role of hexosephosphate in the physiology of voluntary muscle. To buffer the muscle against the large amounts of lactic acid formed in this initial period of asphyxia, two principal mechanisms are provided: the hydrolysis of phosphocreatine and the neutralization of alkali-protein. The first of these is Fiske's theory, which is accepted without reservation, the second has been established by the work of Hill and Meyerhof. As the circulation adjusts itself to the increased demand and the primary oxidative process supplies the necessary energy, any surplus potential energy is utilized to resynthesize the lactic acid and hexosephosphate to the glycogen from which they were derived. The problem of muscular fatigue remains as unsettled and intriguing as it has been throughout the "modern period" of physiology. The precise answer to the question of how to combat the weariness of work cannot be offered until the true cause of fatigue is discovered. The shortening of the hours of labor under the newer governmental provisions for the industries makes rest—the oldest of recommendations—the best prescription for fatigue.

DIPHASIC TUBERCULOSIS

The recent demonstration that many species of pathogenic bacteria "mutate" or "dissociate" into two or more morphologic variants on artificial culture mediums, and that the different pleomorphic "phases" of the same micro-organism are at times of widely different virulence and antigenicity, has introduced a new element of uncertainty into specific antibacterial therapy. For example, future clinicians may have to deal with such complexities as the "mucous membrane phase," "alveolar phase" and "septicemic phase" of the pneumococcus, and with primary, secondary and perhaps tertiary antigenic variants of numerous other specific pathogenic agents. A few such antigenic phases have been definitely established. The successive waves of relapsing fever, for example, are of qualitatively different specific antigenicities. Similar qualitative differences are well established between the primary and tertiary phases of infection with *Spirochaeta pallida*. Both of these micro-organisms, therefore, are definitely 'diphasic' in their biochemical specificities.

Although Thomas's¹ recent studies of the diphasic symptomatology of experimental tuberculosis in rabbits

carefully avoids any reference to the debatable question of antigenic mutation of the injected culture, his two symptomatologies strongly suggest that the tubercle bacillus is diphasic in its virulence and specific antigenicity. The same two phases of the tubercle bacillus are also suggested by the recently reported clinical studies of Rice, Orr and Reed² of Queens University Faculty of Medicine, Kingston, Ont., who have developed a new serologic test with which, they claim, the relative virulence (or antigenic phase) of the causative agents in different cases of pulmonary tuberculosis can be determined, with an 85 per cent coefficient of clinical certainty.

Numerous attempts were made by earlier investigators to develop such a prognostic test. Complement fixation studies, for example, indicated that about 85 per cent of all cases of pulmonary tuberculosis have readily demonstrable antibodies in the blood stream. These tests, however, failed to show any definite correlation between the antibody titer and the progressive or recessive nature of the disease. Even greater difficulties were noted in extrapulmonary tuberculosis, in which fully 50 per cent of all patients tested might show no demonstrable specific antibodies in the blood stream.

In their preliminary work, Dr. Rice and her colleagues immunized rabbits against heat-killed, virulent (or S) cultures of the tubercle bacillus and with the avirulent (or R) dissociates of the same micro-organism. The serums from the two series of immune rabbits were quite different in their relative reactivity to S and R antigens. The serums of animals immunized with S vaccines for example, reacted much more strongly with the S antigen than with the R antigen. The serums of animals immunized with R vaccines fixed about the same amount of complement in the presence of both S and R antigens. Serums from rabbits infected with living virulent S cultures were also tested and gave reactions which suggested that the infectious agent is diphasic in character. The relative reaction to S and R antigens changed during the course of the infection, the change being consistent with the belief that the initial acute, virulent phase of B. tuberculosis often changes to the secondary, avirulent phase during the course of the experimental disease. This observation is in line with Thomas's observed diphasic symptomatology.

Applying the same S/R ratio to one hundred clinical cases of pulmonary tuberculosis, the Canadian investigators noted a correlation between the S/R ratio and the clinical activity of the disease. In actively progressive pulmonary tuberculosis, for example, the S/R ratio was at times as high as 2.9, with an average ratio of 1.73. In slowly progressive cases, 80 per cent of the serums had ratios below 1.73, the average being 1.47. In the stationary or relatively inactive cases the average

¹ Thomas, K. M. J. Exper. Med. 56: 185 (Aug.) 1932.

² Rice, Christine F., Orr, J. H. and Reed, G. B. J. Immunol. 25: 19 (July) 1933.

was 1.22. In a summary of their clinical studies they conclude that an S/R ratio below 1.5 is diagnostic of relatively inactive tuberculosis, with an 85 per cent degree of clinical certainty. An S/R ratio above 1.5 is almost equally pathognomonic of actively progressive tuberculosis.

The Canadian investigators, of course, recognize that their S and R antigens were selected on a purely arbitrary basis. They therefore merely suggest their present "virulence coefficient" as a serologic ratio worthy of extended clinical study.

Current Comment

THE TOXICITY OF DINITROPHENOL

The tremendous activity that dinitrophenol has in stimulating metabolism and producing hyperthermia was referred to somewhat extensively in *THE JOURNAL*, July 15. In that issue there appeared an article on the actions and uses of dinitrophenol by Cutting, Melirtens and Tamter. The Council on Pharmacy and Chemistry also published a preliminary report on the same subject, while *THE JOURNAL* itself called editorial attention to the matter. It has been shown that dinitrophenol enormously accelerates cellular metabolism, and it has been proposed that the substance be used clinically in the treatment of conditions in which acceleration of the metabolic rate may be of value. The Council on Pharmacy and Chemistry in its preliminary report emphasized, however, the limitations to and the possible dangers from the clinical use of this drug and urged that it be used only under strictly controlled conditions. The editorial added emphasis to the same point. Elsewhere in this issue Anderson, Reed and Emerson of San Francisco report on the toxicity of dinitrophenol, and they, too, stress the dangers inseparable from its use. These authors have used dinitrophenol clinically in fourteen cases of obesity, in one of which a severe toxic reaction was encountered. A report of this case is incorporated in their article. It is significant that these authors conclude that it is yet to be demonstrated that dinitrophenol is as safe and satisfactory for weight reduction in human beings as other methods in common use. By a coincidence, San Francisco papers of August 28 reported the death of Dr. Hans Gessnar, a graduate of the University of Vienna, who took an overdose of dinitrophenol with the idea of reducing his weight and, as the paper popularly put it, was "literally cooked to death." It is to be expected that, with the craze that has in the past few years affected the American public, and especially the feminine contingent thereof, for short-cuts to the sylph figure, proprietary products will begin to appear having for their essential drug dinitrophenol. One is already on the market, put out by the R. R. Rogers Chemical Company of San Francisco under the name "Nov-Ben-ol." This preparation is advertised both to physicians and to the public. According to advertising

matter on Nov-Ben-ol, it is a "Magnesia Nitroxybenzol" product and is sold in package of 120 3-gram capsules (33-day treatment) through your physician and the drug trade. It appears, too, that the stuff is also being advertised over the radio. The dangerous possibilities of such exploitation should be obvious.

BERYLLIUM RICKETS

Although scarcely more than a decade has elapsed since in 1922 the existence of a specific antirachitic factor, vitamin D, was clearly established, the importance of this substance and of the comparatively potent ultraviolet rays now looms large in all discussions of rickets. Considerations of this long known disorder, for which there are records that hark back to almost the beginning of the Christian era, nowadays almost always revolve round alleged deficiencies of calcium phosphorus or vitamin D, individually or collectively. It is quite surprising, therefore, to learn that a condition closely resembling if not actually identical with rickets can be produced by inclusion of certain noxious substances into the diet. This is, at least, the situation exemplified by so-called beryllium rickets, recently described by the Canadian investigators Guyatt, Kay and Bramon¹ of the University of Toronto. What they have discovered is purely an outcome of the experimental laboratory. The larger significance of beryllium rickets lies in the light it throws on some of the factors that really determine the genesis of faulty bone metabolism and growth. It was observed, in experimental animals under carefully controlled conditions, that the inclusion of small amounts of beryllium carbonate in the ration resulted in bone lesions having distinct similarities to those of rickets in the same species. The severity of the manifestations bears an approximate relationship to the amount of beryllium ingested. The mineral content of the bones is much diminished. Roentgen and histologic examinations also reveal almost complete failure of the characteristic mineralization. Although beryllium has many points of chemical resemblance to calcium, it does not appear to be deposited in appreciable quantities in the bones. One of the most striking features of the experimental condition is the greatly reduced inorganic phosphorus content of the blood plasma. The explanation is probably to be found in a diminished absorption of phosphate. Any phosphate going into solution in the fluids of the intestine, or liberated by enzymic hydrolysis of phosphoric esters, will, as the Canadian biochemists have pointed out, be immediately precipitated by the beryllium ions resulting from the solution of the basic carbonate in the gastric juice and will thus be rendered unavailable for absorption through the intestinal wall. The resulting type of bone lesion is not preventable by cod liver oil or by administration of viosterol, nor is it amenable to the antirachitic influence of ultraviolet irradiation.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8 55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389 4 meters)

The subjects for the week are as follows

October 3 Mineral Waters
October 5 It May Be Loaded

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM

The subject for the week is as follows

October 7 Too Much Sugar

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

CALIFORNIA

Poisoning from Arsenic on Vegetables—The illness of seventeen patients at Los Angeles Convalescent Home, Montebello, September 19 was traced to arsenic spray used on green vegetables furnished the home the Chicago Tribune reported. Nine other cases of vegetable spray poisoning were recorded in different sections of the city and county it was stated.

University News—A new building costing about \$32,000, has recently been completed at the College of Medical Evangelists. The basement of the new structure will house a museum, and the first and second floors the clinical laboratory of the White Memorial Hospital and space for research work. —Dr. Guy L. Hunner, adjunct professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, conducted a clinic at the University of California Medical School August 17. Dr. John Ruhrah, professor of pediatrics, University of Maryland School of Medicine, Baltimore, addressed the faculty and students of the university September 13 on the history of poliomyelitis. Dr. Charles Weiss, lecturer in pediatrics at the school, will open a course of twelve lectures October 5, on recent advances in bacteriology and immunology. —Dr. Edwin G. Zabriskie, professor of clinical neurology, Columbia University College of Physicians and Surgeons, New York, conducted a clinic in Lane Hall, Stanford University School of Medicine, San Francisco, July 26.

FLORIDA

Whitehurst Dies in Prison—Tyree C. Whitehurst, aged 61, died in the federal penitentiary at Atlanta, September 10 of heart disease. Whitehurst was serving a five year sentence for using the mails to defraud and representing himself as a physician. On a previous conviction of practicing medicine without a license he was given a sentence of a year and a day in the state prison at Raiford. No records have been found to confirm Whitehurst's claim that he was a doctor of medicine. (THE JOURNAL, June 24, p. 2024)

IDAHO

Spotted Fever—Forty-eight cases of Rocky Mountain spotted fever have been reported in Idaho during the current season, with six deaths.

ILLINOIS

Commission to Study Encephalitis—The governor recently appointed a commission of representatives of the Illinois State Department of Health to study the current outbreak of encephalitis in St. Louis. The four physicians are Drs. Hubert S. Houston, Springfield; Sandor Horwitz, Peoria; Henry Reis, Belleville; and William F. Grayson, Granite City.

Public Lecture on Mental Health—Dr. Charles F. Read, managing officer, Elgin State Hospital, will deliver a public

lecture in the Illinois Host House, A Century of Progress, October 11, at 11 a. m., on Mental Health in the Home. The lecture is sponsored by the women's auxiliaries to the Illinois State Medical Society and the Chicago Medical Society. Luncheon at \$1.35 will be served in the Trustees Lounge. Reservations for luncheon should be made with Mrs. William R. Cubbins, 425 Arlington Place, Chicago, before October 8.

Society News—Dr. Thomas P. Foley, Chicago, addressed the Will-Grundy County Medical Society at Joliet, September 20, on medical legislation. —Dr. John J. McShane, Springfield, addressed the Morgan County Medical Society, September 14, on epidemic (lethargic) encephalitis, and Dr. Hubert S. Houston, Springfield, tuberculosis testing of children at the state fair. —At a meeting of the De Kalb County Medical Society in Sandwich, September 28, Dr. Clement R. Martin, Chicago, spoke on anorectal diseases. —A joint meeting of the Fulton and Schuyler county medical societies, September 6, was addressed by Drs. John De J. Pemberton and Frank J. Heck, Rochester, Minn., on Rational Treatment of Hyperthyroidism and Diagnosis and Treatment of Pernicious Anemia, respectively. —Dr. Joseph C. Doane, Philadelphia, addressed the staff of the Paris Hospital, Paris, September 7, on Effect of Opium on the Commerce Literature, Medicine and the Morals of the World.

Chicago

Dr. Meyer Will Give Gehrman Lectures—Karl F. Meyer, Ph.D., director, George Williams Hooper Foundation, and professor of bacteriology, University of California Medical School, San Francisco, will deliver the 1933 Gehrman lectures of the University of Illinois College of Medicine. The lectures will be given at the college, room 423, at 4 p. m. Dr. Meyer's subjects will be:

October 16 Undulant Fever, Bang's Disease and Malta Fever
October 17 Equine Encephalomyelitis
October 18 Psittacosis

IOWA

Contract Practice—The definition of contract practice and the statement used as the basis for all decisions regarding the status of contracts as rendered by the Judicial Council of the American Medical Association, were approved in resolutions of the council of the Des Moines Academy of Medicine and the Polk County Medical Society, adopted August 29. Contracts held by members are subject to review by the council for approval or rejection. The decision of the council shall be final as regards the contract and also the membership status of any member engaged in contract practice.

Society News—Dr. Arthur H. Parmelee, Oak Park, Ill., will address the Linn County Medical Society, October 12, on 'Complications and Care of the New-Born'. —At a meeting of the Des Moines Academy of Medicine and the Polk County Medical Society in Des Moines, September 26, the speakers were Drs. Walter D. Abbott and George A. May, on Diagnosis and Treatment of Head Injuries, and 'Practitioners' Problems in Middle Ear Disease', respectively. —Drs. Charles D. Fenton and E. Grifflin, both of Bloomfield, spoke at the annual picnic of the Appanoose County Medical Society, August 17, at Centerville, on 'Hereditary Diseases and Their Prevention' and 'The Heart in Pregnancy', respectively.

Graduate Courses—Faculty members of the University of Iowa College of Medicine, Iowa City, are conducting courses on pediatrics, obstetrics and internal medicine for the Polk County Medical Society. These courses, which began September 27, will continue two hours a week for a period of ten weeks. Dr. Philip C. Jeans, professor of pediatrics, will discuss nutrition of the infant and child, infectious diseases, mental deficiency, nephritis and emuresis. Subjects covered by Dr. Everett D. Plass, professor of obstetrics and gynecology, will include management of normal pregnancy with certain of its complications, normal labor, normal puerperium, abortion and miscarriage, puerperal infection and toxemias of pregnancy. The course on internal medicine will be given by members of that department as follows:

Dr. Fred M. Smith, Gastrointestinal Disorders
Dr. William D. Paul, Diabetes, Diagnosis and Treatment
Dr. Elmer J. DeCowan, Differential Diagnosis and Treatment of Diseases of the Lungs Causing Chronic Cough and Dyspnea, with Particular Emphasis on Bronchial Asthma
Dr. Horace M. Korn, Heart Disease, Classification, the Diagnosis of Organic Heart Disease and Treatment of Congestive Failure
Dr. Willis M. Fowler, Diseases of the Kidney, Classification of Nephritis, the Distinguishing Features of Each Type and Treatment
Dr. Clarence W. Baldrick, Diseases of the Urinary Organ, Classification, Diagnosis of Each Form and Treatment
Dr. James A. Greene, Diseases of the Throat, Classification, Diagnosis of Hyperthyroidism (Toxic Adenoma and Grave Disease) and Hypothyroidism—Treatment

KANSAS

Outbreak of Food Poisoning—Sixty-five persons including interns, nurses and ten patients, were ill at Bell Memorial Hospital, Kansas City, the *New York Times* reported September 9. The outbreak was believed to be caused by either tainted fish or salad dressing. None of those stricken were in a serious condition, it was stated.

MARYLAND

Personal—Dr Eugene C. Peck has been appointed health officer of Garrett County, effective August 1, and also a deputy state health officer. Previously, Dr Peck was assistant health officer of Newton, Mass.—Dr Henry H. Clay, lecturer at the school of hygiene and tropical medicine in the public health division, University of London, was a recent visitor in Baltimore, studying the organization of public health administration.

Semiannual Meeting—The Medical and Surgical Faculty of Maryland held its semiannual meeting at Cumberland September 28-29, with the Allegany-Garrett County Medical Society acting as host. Dr Abbott R. Walker, Frostburg, president of the latter gave the address of welcome and Dr J. Albert Chatard, president of the medical faculty, the response. The scientific program was as follows:

Dr William F. Williams, Cumberland, Agnathocytosis
Dr Arthur H. Hawkins, Cumberland, The Ideal Cholecystectomy
Dr Samuel M. Jacobson, Cumberland, New Form of Treatment for Acute Gonorrheal Urethritis in the Male
Dr Norman I. Broadwater, Oakland, Acute Infectious Neuroneuronitis

MINNESOTA

Lecture Course—The extension division University of Minnesota, opened a course of lectures for the Renville County Medical Society, September 19, with the following physicians participating:

Moses Barron, anemias, classification and treatment
Harry P. Ritchie, St. Paul, problems in reconstruction surgery
Jennings C. Titzenberg, abortions
Henry E. Michelson, skin
Myron O. Henry, intracapsular fractures of the hip
Jay Arthur Myers, tuberculosis
Frederick C. Rodda, differential diagnosis of meningitis and simulating conditions
Arthur F. Bratrud, treatment of hernia by injection method
George R. Dunn, fractures
Edgar J. Huenekeus, differential diagnosis and treatment of convulsions in childhood

Violation of Basic Science Law—Gerhard John Stramer, an itinerant quack, pleaded guilty to practicing medicine without a basic science certificate, August 18, in the district court at Anoka. Stramer had been calling on people suffering from arthritis, neuritis and similar ailments selling a medicinal preparation called "Trunox." In July he paid a fine of \$50 and costs, following his arrest and plea of guilty to peddling without a license at New Ulm. He was ordered to leave the state which he did, but he returned in the vicinity of Elk River. In the recent charge he was given a suspended jail sentence of six months on his promise to refrain from further violating the laws of Minnesota and to return to Watkins, Iowa, where his family lives. He is a native of Norway, Iowa. Stramer had come to Minnesota from Pasco, Wash., about May 15. He is said to be a garage mechanic by trade.

MISSISSIPPI

Society News—The Issaquena-Sharkey-Warren Counties Medical Society, Vicksburg, was addressed September 12 by Drs. Guy C. Jarratt on congenital syphilis, Edley H. Jones, allergic nasal conditions, and Francis Michael Smith, essentials in smallpox prevention.—At a meeting of the Tri-County Medical Society at Tylertown recently, speakers included Mr. Thomas P. Brady, Brookhaven, on 'The Law of Negligence and Malpractice as Applied to Physicians'; Dr. Robert H. Brumfield, McComb, 'Treatment of Abdominal Pain'; Dr. William H. Frizzell, Brookhaven, 'Our Legal Defense'; and Dr. Oscar N. Arrington, Brookhaven, 'Significance of Abdominal Pain'.—A recent meeting of the Montgomery County Medical Society was addressed in Lexington among others, by Drs. Robert E. Wilson, Greenville, and William H. Curry, Eupora, on autogenous vaccine in pyelitis and congenital pyloric stenosis, respectively.

MISSOURI

Health at St. Louis—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended September 16, indicate that the highest mortality rate (158) appears for St. Louis and for the group of cities as a whole 95. The mor-

tality rate for St. Louis for the corresponding period last year was 104, and for the group of cities, 93. The annual rate for eighty-five cities for the thirty-seven weeks of 1933 was 109 as against a rate of 112 for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population, may tend to increase the death rate.

NEW YORK

Hospital News—A new hospital of twenty-four beds for adults, two for children and eight bassinets was opened, August 10, at Catskill. This is said to be the first general hospital service in Greene County. Dr. George L. Branch is chairman of the medical board of the institution, which will be known as the Greene County Memorial Hospital.

District Meeting—The annual meeting of the first district branch of the Medical Society of the State of New York will be held at Grasslands Hospital, Valhalla, N. Y., October 11. The scientific program will be devoted to tuberculosis, with Drs. Howard Lihenthal and J. Burns Amberson, Jr., New York, as speakers, and the heart, with Drs. James F. Rooney and Frederick C. Conway, Albany, and Lewis M. Hurvath, Boston, as speakers. Dr. George C. Adie, director of surgery at Grasslands, will present an operative clinic and case demonstration in chest surgery. At the luncheon a symposium on state society problems will be presented by Drs. Frederick H. Fiherty, Syracuse, and Daniel S. Dougherty, New York, president and secretary, respectively, of the state society, and Orrin S. Wightman, New York, editor of the *New York State Journal of Medicine*.

Recommendations on Conduct of Medical Practice—The medical economics committee of the Medical Society of the County of Nassau, after a study of the report of the Committee on the Costs of Medical Care and of the medical situation in Nassau County, has issued recommendations concerning medical practice. The committee concluded that no fundamental changes are needed but that certain changes that will bring medical practice in line with modern social and economic conditions are necessary. First the committee urged the formation of a county health unit and the adoption of the 'Detroit plan' of cooperation between the health department and practicing physicians. Continuance and development of the extension of welfare aid for illness with advice and cooperation of the medical society were also recommended. In this connection it was suggested that hospital insurance plans be studied immediately. Other recommendations dealt with representation of physicians on hospital boards and health departments and the control of qualifications for specialists.

New York City

Personal—Dr. Leopold Lichtwitz, formerly of the Rudolf Virchow Hospital, Berlin, has been appointed chief of the medical division of Montefiore Hospital, succeeding Dr. Bernard S. Oppenheimer, who resigned to devote more time to his duties at Mount Sinai Hospital. Dr. Lichtwitz will serve on a part-time basis.—Dr. Aaron S. Blumgarten, chief of the department of endocrinology, Lenox Hill Hospital, will give twelve lectures on endocrinology at the New School for Social Research, 66 West Twelfth Street, beginning October 6.

Window in Cathedral—The first stained glass window to be completed for the Cathedral of St. John the Divine represents the 'Glorification of Healing, Physical and Mental,' according to a recent description in the *Boston Transcript*. The window, which was to be set in place during the past summer, is 26 feet high and was to be set 20 feet above the floor of the church. The design is composed of medallions geometrically arranged. In the center are representations of the biblical miracles of healing, with subsidiary compositions giving an outline of medical history from Imhotep to the present. The figures include Hippocrates, Galen, Avicenna, Pasteur, Lister, Florence Nightingale, Morton, Father Damien and Edith Cavell.

Prolongation of Life of Diabetic Patients by Insulin—A study of persons who have died of diabetes in New York since 1903, reported in the bulletin of the city health department, shows that the introduction of insulin in 1922 has brought about a definite lengthening of the lives of persons with the disease. In making the compilation, the "median age" which represents the age to which exactly one-half of all the persons lived whose death was registered in any particular year, was used instead of the average age. The median age at death for men rose from 56 in 1903 to 61.5 in 1932, that for women rose

from 59.5 in 1903 to 62 in 1932. The average age was also computed and showed an increase from 51.3 to 60 for men and from 57 to 62 for women.

NORTH CAROLINA

Society News—Physicians of Charlotte arranged a practical course in general medicine for practitioners of the state September 4-7. A variety of subjects was included in the discussions, which were led by about thirty Charlotte physicians. No fee was charged.—Dr. Gibbons W. Murphy addressed the Buncombe County Medical Society, Asheville, July 3, on "Giant Cell Tumor of the Spine."

OHIO

Hospital Anniversary—The fiftieth anniversary of the Women's and Children's Hospital, Toledo, will be celebrated October 6. The occasion will also mark the twenty-fifth anniversary of the service of Dr. Walter W. Brand as chief of staff. Clinics will be held in all departments of the hospital in the morning, and the afternoon will be devoted to ward walks and demonstrations by special departments. Dr. Wingate Todd, Henry Willson Payne professor of anatomy, Western Reserve University School of Medicine, Cleveland, will be the speaker at an evening meeting at the headquarters of the Toledo Academy of Medicine. His subject will be "Child Development."

Personal—The Hardin County Medical Society held a special meeting and dinner at Spring Grove September 21, in honor of Drs. William N. Mundy, Forest, and James S. Hedrick, Dunkirk, who have completed fifty years in the practice of medicine.—Dr. George T. Blydenburgh, Kings Park, N. Y., has been appointed director of the department of student health at Ohio Wesleyan University, Delaware.—Dr. Forest C. Haney, Columbus, was elected president of the Ohio State Medical Golfers' Association at the recent annual meeting in Akron.—Dr. John H. Hayes, Columbus, of the state department of health, has been designated health commissioner of Mansfield to serve during the absence of Dr. Millard C. Hanson, who will spend a year studying at Yale University under a fellowship from the Rockefeller Foundation.

Physicians of Northwestern Ohio to Meet—The eighty-ninth annual meeting of the Northwestern Ohio Medical Association will be held in Tiffin October 3. On the program will be the following physicians:

Donald Putnam Abbott, Chicago, Differential Diagnosis and Treatment of Diarrhea.
John W. Carmack, Indianapolis, Sinusitis in Children.
George M. Curtis, Columbus, Iodine Metabolism in Goiter.
Carroll S. Wright, Philadelphia, General Treatment of Syphilis.
Philip Lewin, Chicago, Arthritis.
Descom C. McKenney, Buffalo, Anorectal Problems in Everyday Practice—Their Management.
John D. Camp, Rochester, Minn., Roentgenologic Findings in the Less Common Lesions of the Upper Gastrointestinal Tract.

Dr. George E. Follansbee, Cleveland, chairman of the Judicial Council of the American Medical Association, will make an address at the banquet on "Medicine—A Profession or a Trade?"

OREGON

Personal—Dr. Elmer E. Goucher, McMinnville, was guest of honor at a meeting of the local chamber of commerce, on the occasion of his completion of fifty years in practice in the city.

Society News—Dr. William W. P. Holt, Medford, presented a paper on enuresis before the Jackson County Medical Society, Ashland, recently.—At a meeting of the Eastern District Medical Society at Ontario August 26, speakers included Drs. James Tate, Mason, Seattle, on Problems of Cholelithiasis; Richard B. Dillehunt, Portland, Treatment of Injuries of the Ankle Joint; Arthur C. Jones, Portland, Physical Measures of Use to the General Practitioner; and Albert E. MacKay, Portland, president of the Oregon State Medical Society, on work of the association.

PENNSYLVANIA

State Medical Meeting—Among the features of the eighty-third annual session of the Medical Society of the State of Pennsylvania at Philadelphia, October 2-5, will be a public meeting Wednesday evening, October 4. Dr. Morris Fishbein, Chicago, editor of *The Journal*, will give an address on "Changes in Medical Practice." Dr. Fishbein will also speak earlier in the evening at a dinner given by the Woman's Medical College of Pennsylvania to women members of the state society, on "The Renaissance of the General Practitioner."

The annual smoker will be held Tuesday evening at the Bellevue-Stratford Hotel and the annual golf tournament, Monday, October 2, at the Manufacturers Country Club at Oreland. The scientific program was noted in *THE JOURNAL*, September 23, page 1008.

PHILADELPHIA

Dr. Walter Lillie Comes to Temple University—Dr. Walter I. Lillie, associate in ophthalmology at the Mayo Clinic, Rochester, Minn., since 1921 has been appointed professor of ophthalmology at Temple University School of Medicine. Dr. Lillie is a graduate of the University of Michigan Medical School and the University of Minnesota Graduate School of Medicine and has been instructor of ophthalmology in the latter school.

TENNESSEE

Society News—Dr. Joseph A. Hardin, Sweetwater, was elected president of the East Tennessee Medical Association and Dr. Henry A. Callaway, Maryville, secretary, at the annual meeting in Knoxville September 12. Among speakers were Drs. Lloyd E. Dyer, Greenville, presidential address on progress of medicine; Edwin L. Ellis, Maryville, relative value of infant foods; Robert C. Kimbrough, Madisonville, hypertension; Edward T. and Cecil Newell, Chattanooga, fractures of the lower third of the leg; Jefferson C. Pennington, Nashville, prostatic resection; and Fred W. Rankin, Lexington, Ky., cancer of the colon.—Dr. Edward T. Brading and John W. Wallace addressed the Washington County Medical Society, Johnson City, August 17, on "Pathologic Physiology of Nervous Disorders" and "Allergy in Children," respectively.

TEXAS

Society News—A symposium on ovarian physiology and pathology was presented before the Dallas County Medical Society, Dallas, September 28, by Drs. John L. Goforth, Gomer F. Goff, and Henry H. Turner, the latter of Oklahoma City. Dr. Wilmer L. Allison, Fort Worth, addressed the society, September 14, on encephalitis, and Dr. John V. Goode, on skin grafting.—Drs. Howard R. Dudgeon, Waco, and George W. McCoy, of the U. S. Public Health Service, Washington, D. C., addressed the Navarro County Medical Society, August 8, at Corsicana, on "The Role of Fibrous Connective Tissue in Disease and Typhus Fever," respectively. Corsicana recently carried out an intensive campaign to eradicate rats to combat the spread of typhus fever.

Bexar County Society in Permanent Home—The Bexar County Medical Society and the Bexar County Medical Library Association have recently acquired a new home in San Antonio. The building is a former private home in a beautiful residence section according to the *Texas State Medical Journal* with three large rooms for the library and a dining room on the first floor and an auditorium with a capacity of 250 on the second. The development of the medical library is attributed to the leadership of the late Dr. Frank Paschal, who began advocating it as early as 1900. The nucleus of the library was actually formed in 1912 though the movement to place it on its present basis was not made until 1919 when the society first acquired a building as headquarters for meetings and for the library.

VERMONT

State Medical Meeting—The one hundred and twentieth annual session of the Vermont State Medical Society will be held in Barre, October 5-6, at the state armory. The speakers will include:

Dr. Dean Lewis, Baltimore, President, American Medical Association.
Dr. Colin C. Stewart, Jr., Hanover, N. H., Neurofibromatosis in Children.
Dr. Frank R. Ober, Boston, General Aspects of Chronic Arthritis.
Dr. Howard W. Haggard, New Haven, Conn., The Function of the General Practitioner.
Dr. John M. Wheeler, New York, Exophthalmos as a Diagnostic Sign.
Dr. Hugh Auchincloss, New York, Infections of the Fingers and Hand.
Dr. Clarence H. Beecher, Burlington, Management of Certain Cardiac Disorders.
Dr. Irving Mayo, Jr., Westminster, Health of Normal Boys.

Dr. Lyman Allen, Burlington, president of the society, will deliver his official address Thursday afternoon, October 5, and Dr. John H. Blodgett, Bellows Falls, vice president, will give his address Thursday forenoon. A symposium on recent advances in medicine and surgery will be presented by the following Boston physicians: Drs. Gilbert Horrah, who will discuss intracranial lesions; Frank H. Lahey, thyroid diseases; Howard M. Clute, jaundice; and Lewis M. Hurvath, heart disease.

WISCONSIN

Periodic Payment Plans and Insurance Laws—The insurance commissioner of Wisconsin in response to a request from the Wisconsin Hospital Association has recently ruled that periodic payment plans for the purchase of hospital care fall under the insurance laws of Wisconsin and can be handled only by duly licensed insurance firms. Insurance has been defined in the Wisconsin courts as a contract whereby one party agrees to wholly or partially indemnify another for a loss or damage which he may suffer from a specified peril; the commissioner pointed out and the fact that the agreement is made between hospitals and individuals or groups of individuals does not take it out of the realm of insurance.

District Meetings—The annual meeting of the sixth council district of the State Medical Society of Wisconsin was held in Green Bay September 9 with Dr. Derm. Lewis Baltimore, President of the American Medical Association, as guest of honor. Other speakers were Drs. Max Cutler and Frederick H. Falls, Chicago, and Reginald H. Jackson Madison. Dr. Lewis also made an address at the evening banquet and Dr. Ralph C. Hamill, Chicago, spoke on mental diseases of children. Among speakers at the summer meeting of the ninth council district of the State Medical Society of Wisconsin, Marshfield August 15 were Drs. Stanley J. Seeger, Milwaukee, on treatment of burns, Charles G. Sutherland Rochester, Minn. roentgenology in diagnosis of bone lesions and John S. Coulter, Chicago, physical therapy in treatment of fractures. The eleventh council district of the State Medical Society of Wisconsin and the Interurban Academy of Medicine held a joint meeting in Superior August 3 with the following speakers: Drs. Francis D. Murphy, Milwaukee on high blood pressure, Stanley J. Seeger, Milwaukee treatment of burns, Leo G. Rigler, Minneapolis radiology and Walter A. Fansler, Minneapolis cancer of the rectum. Drs. Gerz de Takats, Chicago and Reginald H. Jackson Madison among others, addressed the annual meeting of the fifth council district of the State Medical Society of Wisconsin at Two Rivers September 7, on Buerger's disease and sacro iliac sprains, respectively.

GENERAL

Society News—Dr. William Wayne Babcock, Philadelphia was elected president of the American Association of Obstetricians Gynecologists and Abdominal Surgeons at the recent annual meeting in Lucerne, Que.—Robert Jolly, superintendent of the Baptist Hospital, Houston Texas was chosen president-elect of the American Hospital Association at its annual convention in Milwaukee September 14. Dr. Nathaniel W. Faxon, Rochester N. Y. was installed as president.

International Body to Coordinate Chemical Literature—The International Office of Chemistry" has recently been created with headquarters in Paris with the following purposes: to render accessible to interested persons the existing literature of chemistry, to facilitate the registering, filing and diffusion of the literature now in course of production and to insure coordination between documentation in chemistry and that of other fields of scientific knowledge. The address of the new organization is 49, Rue des Mathurins, Paris 8.

Prevalence of Infantile Paralysis—Opening of public schools in Hackensack, N. J., was deferred indefinitely September 15, because of an outbreak of infantile paralysis. Theater managers agreed not to admit children under 16 for the same reason.—Fourteen cases were reported in Youngstown, Ohio, September 6 and opening of schools was delayed one week with the prospect of longer delay until the number of cases declined.—Schools in Summit Hill, Pa. were closed September 6, with the appearance of one case in the town.—Prevalence of the disease in Illinois was reported to be heavier than in 1932, with 118 cases since June 1 as compared with 89 cases for the corresponding period of 1932.—*Health News*, the bulletin of the New York State Department of Health stated, September 4 that cases of infantile paralysis had been more numerous than usual in New York City since the middle of July. Eighty-eight cases were reported in New York in July and 307 cases in the first twenty-five days of August. This total is said to be larger than that for any of the past twenty years except the epidemic years of 1916 and 1931.

American Public Health Association—The sixty-second annual session of the American Public Health Association will be held in Indianapolis October 9-12 with headquarters in the Clavpool Hotel under the presidency of Dr. John A. Ferrell, New York whose official address will be America's Contributions and Problems in Public Health. The second Institute on Health Education under the auspices of the public

health section, will be conducted October 7-9, under the direction of Dr. Iago Goldston, New York. Its theme will be 'The Psychology of Health Education'. The preliminary program of the public health meeting, includes the following speakers:

Dr. Morris Lishbein, editor of THE JOURNAL, Chicago Responsibility for the Health Program

Dr. Wilson G. Smith, Boston and Dr. Frederick S. Leeder, Brookline, Mass. Epidemiology of Lobar Pneumonia

Dr. Carey P. McCord, Cincinnati Industrial Intoxication Follows Skin Sorption

Dr. Wade H. Frost, Baltimore A View of Environmental Sanitation in the Control of Communicable Diseases

Dr. Charles Bolduan, New York Has Diabetes Become More Prevalent?

Dr. Cass L. Harmon, Cleveland Death Rates from Puerperal Septicemia in Large Cities 1922 to 1929

Dr. William Lloyd Aycock, Boston Exposure as a Factor in the Ag Distribution of Nerves Diphtheria and Poliomyelitis

Dr. William W. Bauer, secretary, Bureau of Health and Public Instruction American Medical Association, Chicago Team Play Between Public Health Nurses and the Medical Profession

In addition to many other speakers, there will be symposiums among others, on the control of food handlers and the detection of carriers among them, public health engineering problems of large communities, microbiologic examination of food products, child health during depression years—economic aspects, filtrable viruses, standard methods for the bacteriologic examination of milk, congenital syphilis. The annual banquet Wednesday will be a memorial session to Dr. Walter Reed and his associates on the Yellow Fever Commission. Speakers will be Surg. Gen. Robert U. Patterson, U. S. Army, and Dr. Frederick F. Russell, director of the International Health Board of the Rockefeller Foundation.

FOREIGN

Prices of German Periodicals—The German Booksellers Association has taken action concerning the prices of scientific periodicals. The following code of practice was recently agreed on:

1 Publishers of all scientific journals must specify the number of parts or volumes and the annual subscription price before the start of a new volume or publication year and must keep within that limit for the period agreed to.

2 Medical and scientific periodicals now published at inflated prices should be reduced not less than 20 per cent in price and contents for 1934.

3 The Boersen Verein finds the foregoing points of utmost importance and to ignore them would be to repudiate its obligations to its members.

4 The Association of German Universities expects that publishers, editors and contributors will abide by the specifications in paragraphs 1 and 2 and also will reject any material (especially dissertations) that really should not form part of a journal.

5 Both the Association of German Universities and the Boersen Verein are of the opinion that through limitation of the contents the size of the journals will be reduced. Also, the material offered should be more concise and so presented as to increase the value of the journal.

Government Services

U S Public Health Service

Surg. Octavius M. Spencer relieved at Chicago and assigned at Ellis Island.

Surg. Frank M. Faget relieved at Cleveland and assigned at Mobile. Asst. Surg. George G. VanDyke relieved at New London and assigned at El Reno, Okla.

Passed Asst. Surg. Noka B. Hon relieved at New Orleans and assigned at marine hospital, Mobile, Ala.

Asst. Surg. (R) Henry H. Duke relieved at New York and assigned to U. S. Coast Guard Cutter *Seneca*, San Juan, P. R.

Medical Director Hugh De Valin relieved at Berlin, Germany and assigned at American Consulate, Naples, Italy.

Surg. Lieuten. M. Rogers relieved at Denver and assigned at Springfield, Mo.

Acting Asst. Surg. Ratford T. Warnock relieved at Portland, Maine and assigned at marine hospital, Savannah, Ga.

Asst. Surg. Leroy E. Burney relieved at Cleveland and assigned at Hot Springs National Park, Ark.

Passed Asst. Surg. Albert T. Morrison relieved at Belfast, Ireland and assigned at American Consulate, Dublin.

Surg. Albert E. Russell relieved at Washington, D. C. and assigned at marine hospital, Norfolk, Va.

Surg. William L. Smith relieved at Norfolk, Va. and assigned at marine hospital, Stapleton, N. Y.

Chemical Aspects of Life

At the annual meeting of the British Association for the Advancement of Science the president Sir Frederick Gowland Hopkins, professor of biochemistry at Cambridge and president of the Royal Society delivered an address entitled 'Some Chemical Aspects of Life'. Almost the founder of biochemistry and its most distinguished exponent he gave a brilliant and subtle interpretation. Life he said has one fundamental attribute—the arrest of the steady increase of entropy displayed by all the rest of the universe. But there is no evidence that life evades the second law of thermodynamics; it only interposes a barrier and dams up a reservoir of energy which provides a potential for its remarkable activities. The arrest of energy degradation in living nature is indeed a primary biologic concept. Every living unit is a transformer of energy; however acquired and biochemistry is deeply interested in the transformations. Its development belongs almost entirely to the present century. The president's special theme was the importance of molecular structure in determining the properties of living systems. He wished his audience to believe that molecules display in such systems the properties inherent in their structure even as they do in the laboratory of the organic chemist.

CATALYSIS

When colloid chemistry first brought its indispensable aid to biochemistry there was a tendency to discuss its bearing in terms of the less specific properties of colloid systems: phase surfaces, membranes and the like, without sufficient reference to the specificity which the influence of molecular structure wherever displayed, impresses on chemical relations and events. If the colloid structures did not display highly specialized molecular structure at their surface no reactions would occur, for here catalysis occurs. Were it not equipped with catalysts every living unit would be a static system. The catalysts of a living cell are the enzymic structures that display their influence at the surface of colloid particles or at other surfaces within the cell. Current research continues to add to the great number that can be recognized or separated from living tissues. A molecule within the system of a cell may remain inactive until at one such surface it comes in contact with an enzymic structure which displays certain adjustments to its own structure. Then it becomes activated and enters on some definite path of change. The president emphasized the high specificity of enzymic catalysis. The enzyme is in general adjusted to come into effective relation with one kind of molecule only. A living cell is the seat of a multitude of reactions which must be highly organized if it is to retain its identity. They must return to dynamic equilibrium after disturbance. Materials for the maintenance of the cell enter it from the environment. Discrimination among them is primarily determined by permeability relations but of deeper significance is the specificity of the cell catalysts.

COORDINATION OF THE TISSUES: THE ACTION OF THE NERVOUS SYSTEM

In the higher organisms tissues chemically diverse differentiated in function and separated in space react on one another through chemical agencies transmitted through the circulation which thereby coordinate the activities of the body as a whole. It is true that the nervous system is the highest organizing influence but this is exerted through the properties of chemical molecules. In the control of the heart by the vagus it has been

shown that the impulses liberate acetylcholine within the organ. The artificial injection of this substance reproduces in every detail the effects of vagus stimulation. Moreover evidence is accumulating that in the case of other nerves belonging to the same morphologic group as the vagus the same liberation of acetylcholine accompanies activity.

HORMONES

From substances produced temporarily and locally to translate for the tissues the message of nerves the speaker passed to those which carry chemical messages from organ to organ—hormones. They are produced continuously in specialized organs and each has its special seat or seats of action. The profound influence of thyroxine—a substance of no great complexity—in maintaining the harmonious growth of the body and controlling metabolism is well known. Epinephrine again a relatively simple substance maintains a number of important physiologic adjustments.

The most recent growth of knowledge in regard to hormones is the remarkable relations to sexual functions. When an ovum ripens and is discharged estrin is produced in the ovary and brings about changes that make fertilization secure. The new tissue of the corpus luteum also produces a special hormone to this end. These two hormones must act alternately. How is this brought about? Just as the higher centers of the brain coordinate the activities of the lower centers so hormones functioning at so to speak, a higher level of organization coordinate the activities of other hormones. The hormones of the anterior pituitary circulate to the ovary and control its activities.

VITAMINS

Hormones and vitamins should not be separated too widely in thought. It is true that the former are produced in the animal body, the latter supplied by the diet. But it has been shown that some species of animals can form vitamins which then must be regarded as hormones. Knowledge of the molecular structure of hormones and vitamins is growing rapidly and within a few years will be extensive enough to allow a wide view of the correlation between molecular structure and physiologic activity.

Color and the Vitamin Content of Butter

Dr. Lauder, president of the Agriculture Section, showed that the popular view that yellow milk is the best rests on a scientific basis. Milk and butter produced in summer when cows are at pasture, is yellow and this is associated with the presence of carotene or vitamin A. On the other hand winter milk produced when cows are stall fed is much whiter and its content of carotene or vitamin A is much lower. Incidentally this shows the importance of prohibiting the artificial coloration of milk and cheese. The problem is how to provide during winter food with the necessary amount of carotene or vitamin A. Experiments on the drying of grass at the agricultural research station of Berkshire have shown that grass can be rapidly dried at 200 degrees in a band with scarcely any loss of digestive or nutritive properties and what is more surprising, with only a small loss of carotene.

Decline of Intelligence Endangers Civilization

In the Section of Psychology Dr. Hurst of Cambridge argued that intelligence in Great Britain, the United States and other leading countries was declining so rapidly as to endanger civilization as the result of the falling birth rate. Recent intelligence tests in England, the United States, France, Holland and other advancing countries showed a rapid decline of the intelligence index of the population, namely the percentage of the five high grades of intelligence. This he attributed to the much higher decline of the birth rate among the more intelligent classes than among the less intelligent. He advocated imme-

direct action on biologic lines. This could be financed by a transfer of a small portion of the large grants now expended on those of mediocre and low intelligence.

Eminent Sons of Elderly Fathers

In the Anthropological Section, Mr. A. F. Dufton maintained the interesting thesis that the older the father the more likely the son to attain eminence. He circularized fellows of the Royal Society, members of parliament and herd mistresses of schools on the ages of fathers when sons were born. He found that the proportion of sons who attained eminence was twice the normal when the father's age was 45 as when under it, ten times the normal when his age was 60, and fifty times the normal when it was 70.

The Rôle of the Chlorides in Operative Shock

Mr. Robineau has contributed an analysis of the conception that assigns great importance, in accidents due to postoperative shock, to hypochloridemia. Prof. F. Legueu, B. Fey, Palozoli and Mlle. Lebert have also presented a communication to the Academy of Medicine. According to Legueu in seeking to comprehend the mechanism of this source of postoperative disturbance one is surprised to find that the chlorides diminish simultaneously in the blood and the urine. In general, there is not a loss but merely an abnormal distribution of chlorides. Numerous experiments on animals (wounds of the liver, kidneys or muscles) have shown that the chlorides become localized in the region of the operative wound, where one finds a constant local hyperchloriduria, which progresses for several days after the operation, the time period varying with the importance of the traumatism, while the degree of traumatism explains largely the diminution of the chlorides in the blood. One may find here a reason for the gravity of certain operations that are particularly mutilating, such as prostatectomy. With the disturbance of the chlorides, the molecular equilibrium is disturbed, the kidney is affected and its secretions are reduced, and an azotemia is produced until the introduction of salts by an injection of hypertonic solution of sodium chloride reestablishes the equilibrium. This new fact explains a number of the accidents due to traumatic shock heretofore attributed to intoxication by nitrogenous substances. It affords a valuable therapeutic indication, since injections and lavages of a 30 per cent solution of sodium chloride are found to be valuable in all these states. The large postoperative injections of physiologic solution of sodium chloride, so much employed thirty years ago, are again coming into use.

Sterilization of Drinking Water

The problem of securing an abundant supply of pure drinking water for the villages of France is one of great interest to parliament. For many years this movement has stood at the head of various programs for the improvement of health, but in order to complete the program it would be necessary to appropriate several billion francs, and that appears to be out of the question for, according to law, the communes must furnish at least half of the funds needed for new installations, the government supplying the remainder. An endeavor is being made to discover more economical methods for the sterilization of water. Two methods are used at present. The first is ozonization which might easily be installed wherever electric power is cheap for example, in mountainous regions. France has created so many plants for the production of electricity by water power that it has an excess of electric power current. The second method for the purification of water is that introduced by P. Bureau-Barilla and termed 'verdunization,' because

it was used to supply pure water to the army that defended Verdun during the war. It consists in the addition of variable quantities of chlorine, depending on the condition of the water. The excess of chlorine is removed afterward by the use of a small quantity of potassium permanganate, if necessary. This method is economical and easy to install. Many cities have adopted it. The health commission of the chamber of deputies, on receipt of the report of Dr. Goujon, has pronounced in favor of verdunization. But the industrialists who were counting on furnishing the materials for ozonization have launched a campaign of opposition, supporting their contentions on the testimony of Dr. Roux, director of the Pasteur Institute, whose disinterestedness is unimpeachable. Dr. Roux has stated that ozonization is the most perfect method of purification because it destroys radically all living micro-organisms. He recognizes, however, from the objective point of view, the value of purification by means of chlorine when circumstances prevent the previous filtration of impure water. Dr. Goujon, who defends verdunization, has replied to Dr. Roux in a public statement in which he raises objections to ozonization. Goujon admits that ozonization is a perfect method, but only in the laboratory, as it requires the use of a gas that is thoroughly dry, which is not practicable in installations on a large scale. If the gas is not absolutely dry there develop compounds which may be dangerous. One of these compounds, nitrous acid, combines with choline in the human organism and forms a poison that may cause death, by arresting the heart. Doubtless the quantity formed in this case is too small to be fatal, but harm may result from quantities too small to be measured when it is ingested in drinking water. There is, therefore, no direct antagonism between the declaration of Dr. Roux and that contained in the report published by Dr. Goujon.

Vaccination Against Diphtheria

Prof. G. Ramon and his co-workers P. Nelis and J. Lacombe have introduced a new form of technic in vaccination against diphtheria, which they described in a communication addressed to the Société de biologie. Children who had positive Schick tests were subjected to antidiphtheritic vaccination in the form of two injections of 1 cc each of an anatoxin with a titer value of 30 antigenic units. The injections were given with an interval of three weeks. The Schick control test applied to the 222 children thus vaccinated proved negative in 99 per cent. Thus, whether one uses anatoxin having a potency of 20 units, in two injections of respectively 1 and 2 cc, equal to 60 units or whether one vaccinates with two injections (1 cc each) of anatoxin with a potency of 30 units, or a total of 60 units, one realizes an advantage over the old technic (three injections of anatoxin of 10 unit potency), for the immunity as shown by the negative Schick test is conferred on virtually all the persons vaccinated, while only two injections are given in place of three.

Treatment of Rheumatism with Bee Venom

Prof. Maurice Perrin, of the Faculté de médecine de Nancy, and Mr. Alain Cuenot, have published a report on the action of bee venom on patients with rheumatism. Their purpose at first was to test the popular belief in this treatment, a belief that is ancient, being mentioned by Hippocrates. They began their research with great skepticism. Their surprise was great when they found that this action of bee venom, studied by several ancient authors, is bona fide. Their report covers twenty convincing observations bearing on arthritis deformans, articular rheumatism, arthritis, rheumatoid pains (also muscular), lumbago and sciatica. Their technic is simple. The bees, collected in a bottle placed before the opening in a beehive, are taken up one by one with forceps and placed in a cupping glass reposing on a sheet of paper. When a sufficient number of bees

have been transferred, the cupping-glass is placed on the skin of the patient at the site chosen and the sheet of paper is quickly withdrawn. The bees immediately begin to sting, but the pain caused by the stings is much less in a person affected with rheumatism than in a normal person as has been observed for a long time. While the stings must be applied to the painful spot, the action of the venom may be exerted *a distance*. The treatment often requires two months. Thirty bees stinging the patient at one sitting, every three days, constitutes an adequate treatment. Perrin has secured a solution of bee venom, which can be used hypodermically with the same results. With flamed forceps he extracts the venom sacs and transfers them to a receptacle with absolute alcohol. It is later dried in a vacuum and preserved in an ampule of physiologic solution of sodium chloride, in which the venom quickly dissolves.

New Regulations Concerning Vivisection

In 1930, new regulations were established in Prussia, which permitted experiments on living animals only for purposes of important research, and then only under prescribed conditions, with avoidance of superfluous experiments for demonstration purposes, for which film presentations might be substituted. All serious-minded scientific investigators supported this ministerial order (THE JOURNAL, Aug 13, 1932, p 574).

August 17, Goring, chairman of the Prussian ministerial cabinet, issued an order to go into effect immediately that "vivisection of animals of whatsoever species is prohibited in all parts of Prussian territory. The chairman of the cabinet has instructed the ministries to present to him without delay the text of a law incorporating this provision. Until the promulgation of this law persons who engage in vivisection of animals of any kind will be removed to a concentration camp." The applications to serious scientific research will be defined and explained in the near future. Bavaria, also has prohibited vivisection. It is generally understood that these prohibitions are to be regarded as the prologue to a corresponding federal law for the protection of animals, the elaboration of which is already under way by the federal ministry of the interior and the federal bureau of health. In the meantime the basis of application will be that necessary diagnostic and therapeutic tests on animals, such as insulin control and the diagnosis of renal tuberculosis, will be permitted. Medical research will have to wait to be sure, for the proclamation of the new legislation. In an announcement of the federal minister of the interior, it is expressly stated that "consideration will be given to the requirements of science."

The Physiology of Work

At the convention of the Kaiser-Wilhelm-Gesellschaft zur Forderung der Wissenschaften Professor Atzler, the director of the Kaiser-Wilhelm Institut für Arbeitsphysiologie in Dortmund, delivered an address that attracted wide attention. The province of the physiology of work is to teach a person engaged in a fixed occupation how he can utilize his energy to the fullest extent without fearing that he will wear out prematurely. In the case of heavy physical work the problem is comparatively simple, the solution being reached by establishing with the aid of the respiratory apparatus the most favorable work load and the most favorable work tempo for every type of work, for example hammering, shoveling or the lifting of heavy weights. These computations having been made one has the basis for reckoning the length of the necessary rest periods. The problem is more difficult in the case of light easy work in which one group of muscles after the other becomes charged with fatigue products and in which particularly the nerve

centers are subjected to a severe strain. In this type of work, fatigue injuries from which one may never completely recover will sometimes result. In order to avoid such injuries one must correctly adapt the working intensity to the capacity of the human organism, which fluctuates according to definite "laws" and varies at different hours of the day. This capacity, or potential performance, usually rises gradually in the morning over a period of from thirty to sixty minutes, and then remains for several hours at its high level, whereupon it slowly declines but after a certain time rises again.

Great importance attaches, in all work, to the correct number, distribution and duration of the rest periods. As a rule it is advisable in independent work to allow rest periods amounting to at least 5 per cent of the work period. One can apply the rest periods uniformly by taking a few minutes off from each hour, or rest periods of varying length can be introduced during the forenoon and during the afternoon. In planning the arrangements of the work room or yard, one must pay attention not only to the correct location of work material and apparatus but also to what constitutes the best body position for the work in hand. Special importance attaches also to correctly constructed seats, to be used when needed. It is important that one avoids overstraining certain muscles. Above all, the whole work process must be so arranged that compensatory movements are possible. Many types of office furniture take no account of this need.

Tools and machines must be so constructed that the workman is protected against injury. Tools operated by compressed air, for example, may lead to joint injuries owing to their too strong recoil. By application of an ingenious method, it has been possible to register the recoil curve while the workman is working with the compressed air tools. Examination of these curves has enabled the manufacturers to make such changes in the construction as will eliminate the recoil.

It belongs to the physiology of work to take account of the diet of the workman. A scrutiny of the workman's diet, as Atzler pointed out, has shown that not only highly valuable protein substances and vitamin-containing foods are lacking but also, to a great extent, important mineral salts, particularly phosphates. An insufficient amount of milk and dairy products for example, is consumed.

"House Pharmacies" Prohibited

For decades, physicians in remote regions have been permitted, after a special examination to conduct a so called house pharmacy, in which they themselves were allowed to prepare the necessary medicines. This was a recognized exception to the pharmacy privilege. Now the Prussian ministry of the interior has ordered the cancellation of permits to conduct these house pharmacies. It is pointed out that transportation facilities have improved and that the reasons for house pharmacies seldom hold at present, as physicians can carry with them remedies needed in emergencies. It was explained that house pharmacies not only threaten the existence of the nearest regular pharmacies but also prevent young physicians from settling in rural districts since the older physicians who possess house pharmacies put them at a disadvantage. There is to be however a new investigation to discover whether the need for house pharmacies still exists. The pharmacies of a given district will be required to make arrangements for supplying the population with a reliable drug service.

Cadavers for Instruction Purposes

In previous letters mention has been made of the dearth of cadavers for instruction purposes. The Prussian ministry of the interior now has issued an order the purpose of which is to supply the anatomic institutes at universities with the cadavers needed. Municipalities, local police boards and the authorities

of some other political districts are empowered to deliver to the institutes the bodies of persons who die in infirmaries without friends to claim the bodies and likewise when relatives or acquaintances of the deceased are unwilling to assume the costs of burial.

Lupus Patients and Their Capacity for Work

According to the new regulations of the lupus commission of the German Central Committee for Combating Tuberculosis lupus patients are to be regarded as incapable of working (1) in every case of rapidly progressing infection (2) if the disorder extends to large areas of the body or appears in numerous individual foci (3) in case of extensive involvement of the hands (4) in involvement of the lower limbs if freedom of motion is impaired (5) in involvement of the face which disfigures the patient or causes disgust (6) in involvement of the lips, the buccal and the pharyngeal mucosae and extensive involvement of the nasal mucosa (7) if the sight has become unimpaired by spreading of the lupus infection to the eyelids and to the eyeballs (8) in the event of tuberculous complications affecting the lungs, the glands or the bones. Advanced degrees of involvement of the types cited may establish not only temporary but even permanent incapacity to work or to pursue a gainful occupation. It is significant that the federal bureau of insurance as a supervising body has expressly declared that it has no objections to these criteria from the standpoint of health insurance.

THE NETHERLANDS

(From Our Regular Correspondent)

Aug 5 1933

Gout in the Netherlands

The international bureau of hygiene has published a report by Dr. Josephus Jitta on the incidence of gout in the Netherlands. Research on the incidence of gout among recruits carried out by Dr. Brand in 1917 showed that 6 per cent of 45,000 recruits were affected. He found that gout was almost nonexistent among recruits from the provinces of the North but that it was frequent in the provinces of Utrecht and Gelderland and presented an intermediate condition in the other provinces. In 1918 a research carried out in several cities among the grammar school children notably in Utrecht, Breda, Leeuwarden and Middelburg showed that gout developed respectively in 66, 60, 35 and 17 per cent of the school children. A special commission was appointed to institute an inquiry. Endemic gout does not, however, constitute an imminent danger for the public health. The disease should receive consideration chiefly because it is increasing and because it is found in regions where it was not supposed to exist. The number of cases of thyrotoxicosis are becoming less rare. The increase in the incidence of gout may also be shown by the examinations of the soldiers. In 1925 seventy recruits out of every 10,000 and in 1930 150 recruits were declared unfit for military service by reason of gout. The Netherlands commission attaches to the theory of the lack of iodine as the epidemiologic cause of gout the greatest importance and hence the research was limited to the significance this substance may have in the general development of the disorder.

Mental Patients in the Dutch East Indies

In the *Geneeskundig Tijdschrift voor Nederlandsch Indië* Mr. Van Vullften Palthe discusses the hospitalization of mental patients in the Dutch East Indies. The number of the mentally ill in the Dutch East Indies is not known exactly. Among the natives it is difficult to ascertain the exact percentage because only those in the advanced and dangerous stages are interested in treatment; persons with mild manifestations are unable to comprehend that it is to their advantage to be

interned for treatment. There are about 1,400 temporary internments each year. In these cases the selection is not made by psychiatrists. The patient enters first an institution in which he remains from three to four months, during this period about 7 per cent die. Of the remaining 93 per cent those who show evident signs of insanity remain; the others are dismissed. Syphilis is frequent and is often associated with mental disorders. The institutions for temporary detention and those for internment have been increased but without much improvement in the situation. The system should be radically changed. European methods cannot be employed, for in Europe every mental patient is interned, which in the Dutch East Indies is both impossible and useless.

Prophylaxis of Weil's Disease

The *Verlagen en Mededelingen betr. de Volksgezondheid* publishes prophylactic provisions pertaining to Weil's disease. Thus, disease, it is said, appears to develop chiefly in persons who have bathed in open waters and therefore occurs principally during the bathing season, as may be seen by a comparison of the incidence of the disease during the months of 1932: January 2 cases, February 1, March and April 0, May 1, June 4, July 8, August 36, September 124, October 24, November 4, December 3. The total number of cases for the year was 207, 16 of which had a fatal issue, constituting a mortality of 7.7 per cent. Sporadic cases occurred in all parts of the country. Prophylaxis should be centered on the summer season to prevent the infection of bathers in the occasional bathing places, that is, places outside the regular establishments. The precautions to be taken in this regard should be directed chiefly against rats. The measures adopted should therefore take into account the destruction of rats, the adoption of measures to deprive rats of their food supply and the prevention of rats nesting in the vicinity of bathing places.

New Cases of Syphilis in Northern Part of Netherlands

According to statistics of the university polyclinic of dermatology and of venereology at Groningen, syphilis increased in the northern provinces of the Netherlands during the years 1926-1931. In 1926 nine cases of recent syphilis were recorded at the polyclinic or 0.49 per cent of the total number of new patients, whereas in 1931 ninety-three cases of recent syphilis were admitted for the first time or 5.31 per cent of all the new patients under treatment. V. Düring has held that syphilis always increases during a social crisis.

The National Bureau of Anthropology

The first session of the Netherlands National Bureau of Anthropology was held at the Colonial Institute in Amsterdam. Of special interest was the paper of Dr. de Mol van Otterloo concerning the use of opium in the Dutch East Indies. In 1930 16,000 opium smokers were registered by the excise office. This number comprises only the buyers of opium. The actual number of smokers must be at least twice that number, for many are content to use bootleg opium. Persons become addicted to opium for different reasons: to diminish pain, to break up a cough, to dispel fear and for its stimulating effect. Once the habit is formed they smoke without any particular reason. Opium smokers foregather in groups. There are many sick persons among them, also many unreliable and neglectful heads of families.

Criminal Abortion

The journal *Mensch en Maatschappij* (volume 8, number 1) contains an article by J. Valkhoff on the increase of criminal abortion in the Netherlands, which is especially noticeable among the poorer classes owing to the economic conditions. Most of the abortions are induced by men or women without

medical intervention. In Amsterdam alone there are about 500 abortionists. In Rotterdam the conditions are about the same. In The Hague the proportion is smaller as it is chiefly a residential city. In the rural districts, abortion is not as common as in the cities. The total number of criminal abortions in the Netherlands is placed at 14,600 a year. The author thinks that this figure is too low.

The Airplane Ambulance

The first Netherlands airplane ambulance has recently been completed, an open 'two seater' having been transformed into a closed airplane. The transportation of patients by ambulance airplane can be effected only at regular aviation fields (Soesterberg, Gilze Rijen, Schiphol, Oldebroek, Harskamp, Arnhem, Kamperheide, De Kooy Vught, Venlo, Waalhaven, Flushing, Eelde, Eindhoven and Twente). Requests for such transportation (in emergency cases only) may be made through the Red Cross, Green Cross, White Cross and White Yellow Cross societies and these societies must apply in such cases to the commander of the aviation service in Soesterberg.

The Leprosy Crusade in Dutch Guiana

New regulations have been put into force for the prophylaxis of leprosy which abandon the system of segregation heretofore in use. Henceforth, what will be chiefly sought will be adequate treatment of the patients, the latter being required to observe hygienic precautions. The three objectives of the organization are (1) the early detection of cases particularly among school children, (2) gratuitous treatment of lepers in their homes or in dispensaries with supervision to see that hygienic instructions given them are carried out and (3) treatment in retreats of patients unable to provide for proper treatment at home. This hospitalization is temporary ceasing when the lepers are considered sufficiently improved or when the treatment may be continued at home. J. Lampe stated that the new leprosy service had already ferreted out 1107 cases of leprosy, 249 patients being cared for in the dispensaries of Paramaribo, 195 patients are being treated in their homes in the city or the rural districts of Dutch Guiana, 482 patients have been hospitalized.

Priority in Liver Therapy

The Consiglio nazionale delle ricerche has investigated the alleged priority of Prof. Pietro Castellino, director of the first Clinica medica in Naples, in the treatment of anemias by means of liver therapy. The committee that examined the scientific evidence pertaining to the claims was presided over by Professor Viola, clinical physician of Bologna.

From an account of experimental work published in 1912 by Dr. Pirera, assistant of Professor Castellino, it appears that the latter had administered for some time by mouth considerable quantities of liver sugar to patients, and that such administrations proved highly beneficial. Such therapy was based on the principle that the liver elaborates and throws into the blood stream substances that stimulate the bone marrow, increasing in a most notable manner its activity. Experiments performed by Dr. Pirera on rabbits rendered anemic showed that injections of liver extract induce a reparative hemitopoietic activity of medullary origin much earlier and more intense than the spontaneous activity produced by venesection. There must be assumed, however, a function of the liver consisting in the elaboration of substances of the type of hormones which in small quantities exert a remote but strongly stimulative action on the bone marrow. In case of their absence as a result of a hepatic lesion there is a complete collapse of the

medullary function. Another conception based on these experiments was that of the existence of a special type of anemia, characterized by the fact of being associated with the miopragia of this special function attributed to the liver.

From the examination of the publications on the subject and the results secured by various research workers, the Consiglio nazionale delle ricerche concluded that the priority of the experimental demonstration of the efficacy of liver therapy in anemias belongs to Professor Castellino and to his co-worker Dr. Pirera (1912).

Vaccination Against Tuberculosis

The ministry of the interior has sent to the prefects of the provinces a circular letter on vaccination against tuberculosis, in which it is emphasized that this prophylactic measure the use of which was begun in Italy as early as 1903, is deserving of every consideration. The experimental stage now may be regarded as completed. The Federazione nazionale per la lotta contro la tubercolosi was asked to launch a publicity campaign and to establish rewards for physicians who used such vaccination. The provincial antituberculosis societies have now been requested by the ministry to favor every endeavor in this direction, it being pointed out that vaccines prepared with dead bacilli may be freely employed by all physicians, whereas the use of other vaccines is permissible only in institutes and clinics that furnish adequate guarantees. All vaccinations against tuberculosis should be registered and the persons vaccinated should be carefully supervised by physicians.

The House of Rest for Physicians

The Sindacato nazionale dei medici has taken the initiative in the creation of a 'casa di riposo' for physicians to be erected in Rome on a site facing the Piazza Forlani, close by will be erected a therapeutic center for the benefit of aged physicians, preference being given to those who fought in the World War. In addition to personal gifts the Classe medica italiana has contributed 1,000,000 lire (\$72,000).

Meeting of Academy of Sciences

The Accademia delle scienze medico chirurgiche met recently in Naples, under the chairmanship of Professor Boeri. De Nunno spoke on neoplasms due to roentgen rays. Epitheliomas due to roentgen rays appear to arise from the deeper strata of the epidermis and the derma and to advance toward the bone. The epitheliomatous tufts are often surrounded by granulation tissue and bring about the formation of horn pearls by a process of parakeratosis or dyskeratosis. The reduction and the disappearance of the bone tissue are due to a process of lacunar resorption. The nervous tissue and particularly the nerve terminals have shown themselves to be extraordinarily resistant to roentgen rays. With regard to the pathogenesis of the roentgen epithelioma the observations of the speaker do not support the theory of Ribbert (isolation of the rete mucosum of Malpighi through the effects of proliferating dermic papillae) or that of Borst who ascribes to the rays an aspecific action provoking an inflammatory process with formation of ulcers that spontaneously develop into cancers. According to De Nunno being able to discover direct metaplasia of the malpighian cells at points that were not the sites of ulcers or of inflammatory processes points to a local action of the roentgen rays and furnishes a new contribution to the theory of irritation bringing such neoplasms near to those due to betel, soot, tar or kauri (fire basket).

Lugli spoke of the relation between vasomotor rhinitis and anaphylaxis and emphasized that in many cases of vasomotor rhinitis neither clinical nor laboratory research supplies evidence that justifies belief in the anaphylactic nature of the disorder, the manifestations appearing rather as reflex reactions to stimulations of the nasal mucosa. The speaker holds that the reac-

tions following the introduction of antigens, and, especially, the production of antibodies, are regulated in a reflex manner by excitations of the cellular sensitivity. Sensitization experiments were carried out by the parenteral route in guinea-pigs under anesthesia. The speaker concluded that sensitivity is fundamentally important in controlling in a reflex manner the reactions that lead to the creation of anaphylaxis and immunity.

JAPAN

July 29, 1933

Longevity and Moderation

Dr Nakayama, a school hygienist of Gifu prefecture, after ten years of research has found a way to enjoy longevity. He sent cards to 10,000 people who are more than 80 years of age throughout the country in order to have them record the climate, circumstances, manner of living, hygiene, tastes, and other factors. He reports that living in cities decreases the life span and that aged women are much more numerous than aged men. The places where the aged are most numerous are listed in the following order: (1) a seaside village, (2) a village on an island near the mainland, (3) a town near the sea, (4) a village on a plateau, (5) a village in a level country, (6) a village among the hills, (7) a village in an isolated island, (8) a town in a level country, (9) a town on a plateau, (10) cities, (11) large cities.

The majority of these aged people had long-lived grandparents, parents, and brothers and sisters. They all had from three to five brothers or sisters. Ninety-three of a hundred married unrelated persons. They are found most in the middle classes, the lower classes rank second and the upper classes rank third. The majority proved to be the eldest son or daughter. Most of them were born when the fathers were between 26 and 30 years of age and the mothers were between 21 and 25. An unmarried person seldom enjoys longevity. The majority were agricultural workers; few followed industry, and government officials seldom enjoyed longevity. The aged mostly have a normal constitution, but some are corpulent and few are slender. A tall man lives long, but the short man does not. Seventy per cent of them have a strong frame. Baldness increases as the generation advances (grandfather, 27.8 per cent; father, 29.3 per cent; and the present persons, 37.8 per cent). They now go to bed early and rise late. They generally have led a quiet life. They are not particular about what they eat. Half of them are drinkers but the women are all nondrinkers. In order to live long, one should live in the country or on a plateau. The standard of living should be that of the middle classes.

Increase in Infectious Diseases

From January to the end of July in the districts of Tokyo-fu, the number of cases of infectious disease amounted to 15,167, which is an increase of 3,366 over last year. The largest increase was 812 cases of dysentery, mostly in children from 3 to 7 years of age and one out of two patients died. There were 3,855 cases of diphtheria, an increase of 1,372. The sudden increase is chiefly due to the long drought that occurred. The beds in isolation hospitals in these districts are full. Later in the summer there are usually more cases and so the authorities are much troubled to find more beds. The death rate from diphtheria at present is 16 per cent.

Great Expansion of Sickness Insurance

The social bureau of the home office has planned a remarkable expansion of sickness insurance which has been limited to factory workers. The new plan intends to change the present voluntary application for insurance to compulsory joining. Families will also be included. Besides factory workers insur-

ance will be compulsory in any business, excluding farming, and marine products, in which there are over five employees. This system will include about 1,130,000 additional factory workers, about 70,000 in crews of ships, and about 130,000 workers who engage in other work. This insurance is for laborers. In addition, a system termed "staff sickness insurance" will be established for salaried men who receive less than 150 yen a month, such as officials of the central and local governments, school instructors and office clerks. This is also compulsory and includes their families, a total of about 5,640,000 people. This is absolutely independent of the old insurance.

For those excluded from the foregoing, a voluntary system called "national sickness insurance" will be started. About 1,110,000 persons are expected to join this system.

A vast sum of money to realize these plans will be required of the government.

Rare Medical Books

In an ancient monarchy in the northeastern part of this country there lived a well known physician called Ono Ryuan who practiced Chinese medicine as a family physician of the monarch about 150 years ago. He was noted for his collection of medical books, but since his death they had been missing. This summer his library, called "Kohosen," consisting of more than 1,200 volumes of rare old books on medicine, was by chance discovered at a rich farmer's house in the village where he lived. Professor Muraoka of the Northeastern Medical University judged that they were authentic. This library contains medical books published 500 years ago in China. There are ten volumes devoted to indigenous medicinal plants with a minute explanation of their use. The medical university bought them all.

Personals

Prof. Haruo Hayashi has recently retired as director of the medical department of the Tokyo Imperial University. It is reported that he is going to be elected president of the university in the autumn, when the president's term expires.

On the occasion of celebrating his seventieth birthday recently, Dr. Y. Tashiro, the noted surgical orthopedist and honorary professor of Tokyo Imperial University, received a commemorative offering, and there were about 300 present.

Dr. K. Miyairi, ex-professor of the Imperial University and renowned parasitologist, has donated 3,500 yen as a scholarship fund to the Japan Parasitology Society for a prize for the best paper read in its annual meeting.

Dr. N. Hayashi, who recently retired from his post in the Nagoya Medical University, has established a research institute for the study of tsutsugamushi disease, to which he has devoted his life. His laboratory will give preventive injections free of charge.

Marriages

JOSEPH W. HOLTEY, Ossian, Iowa, to Miss Antoinette C. Hammang of Fond du Lac, Wis., August 21.

CARL ANTON PLATOU, Valley City, N. D., to Miss Inga Rocksvold of Litchfield, in July.

LAWRENCE H. GILMAN, Indianapolis, to Miss Ruth Johnson in New York, August 23.

CHARLES H. COUGHLAN, Iowa City, to Miss Grace Ettlinger of Iowa City, August 5.

DAVID G. MILLER to Miss Pearl Claire Dyer, both of Los Angeles, August 27.

ARNOLD L. LIEBERMAN to Miss Hilda Kahan, both of Gary, Ind., August 27.

WILLIS H. MCKEAN, Kansas City, to Miss Virginia Shelton, August 12.

Deaths

Jeremiah Joseph Corbett ☉ Boston Harvard University Medical School, Boston, 1906 member of the American Academy of Ophthalmology and Oto-Laryngology the New England Ophthalmological Society and the New England Otological and Laryngological Society, fellow of the American College of Surgeons, on the staffs of the Boston City Hospital the Malden (Mass.) Hospital and the Whidden Memorial Hospital, Everett, Mass., aged 55 died, August 24, in Santa Fe, N. M.

Earl Willis Kobler, New York, Columbia University College of Physicians and Surgeons, New York, 1906, member of the Medical Society of the State of New York, at one time instructor in laryngology and otology at his alma mater formerly on the staffs of the Manhattan Eye Ear and Throat Hospital and the Vanderbilt Clinic assistant director of the bureau of hygiene, New York City Department of Health, aged 50, died, August 10

George William Warren, New York Johns Hopkins University School of Medicine, Baltimore, 1901, member of the American Association of Genito-Urinary Surgeons and the American Urological Association fellow of the American College of Surgeons, on the staff of the Lutheran Hospital, aged 57, died, August 24, at Ridgefield, Conn., of heart disease

Ralph Alexander Stewart, Lynbrook N. Y., New York Homeopathic Medical College and Hospital, 1900 clinical professor of surgery at his alma mater fellow of the American College of Surgeons, served during the World War, for many years on the staffs of the Broad Street and Community hospitals, New York, aged 64, died August 22

Robert Holmes Greene ☉ New York, Harvard University Medical School, Boston 1886 member of the American Association of Genito-Urinary Surgeons and the American Urological Association fellow of the American College of Surgeons on the staff of the City Hospital, aged 72, died, August 28, of pneumonia

Harvey Mayor Becker, Sunbury Pa. University of Pennsylvania School of Medicine Philadelphia 1898 member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Oto-Laryngology medical superintendent of the Mary M. Packer Hospital, aged 60, died, August 28

John Pearl Gifford ☉ Randolph, Vt., Dartmouth Medical School Hanover, N. H., 1897, fellow of the American College of Surgeons, preceptor to the University of Vermont College of Medicine, Burlington on the staff of the Randolph Sanatorium, aged 61, died August 30, in the Deaconess Hospital, Boston

Clarence Eugene Sellers, McCullough Ala. University of Alabama Medical Department Mobile 1904 member of the Medical Association of the State of Alabama aged 54 died August 17 in the Atmore (Ala.) General Hospital of a cerebral hemorrhage, as the result of an automobile accident

Josiah Graves Furnish, Covington Ky., Medical College of Ohio Cincinnati, 1877 member of the Kentucky State Medical Association formerly member of the state senate and of the board of health on the staff of St. Elizabeth's Hospital, aged 80, died September 8, at his home in Erlanger, of pneumonia

Ella Blaylock Atherton Nashua N. H. Queen's University Faculty of Medicine, Kingston Ont. Canada 1887, member of the New Hampshire Medical Society fellow of the American College of Surgeons on the staffs of St. Joseph's and Nashua Memorial hospitals aged 73 died September 1

Maximilian Adolph Schurter ☉ Long Beach Calif. Long Island College Hospital Brooklyn 1912 member of the American Academy of Ophthalmology and Oto-Laryngology on the staff of the Seaside Hospital aged 51 died August 22 of coronary sclerosis and pulmonary edema

John G. Keller ☉ Toledo Ohio Toledo Medical College 1900 member of the American Urological Association fellow of the American College of Surgeons on the staffs of the Toledo and St. Vincent's hospitals aged 61 died, August 4 of myocarditis and bronchial asthma

George B. Hamilton, Olney Texas Fort Worth School of Medicine Medical Department of Fort Worth University 1908 member of the State Medical Association of Texas physician and owner of the Hamilton Hospital aged 54 died July 19 in a hospital at Galveston

John Preston Kennedy, Greenwood Miss. Jenner Medical College Chicago 1917 member of the Mississippi State Medi-

cal Association, served during the World War, aged 40, died August 6 in the Mississippi Baptist Hospital, Jackson, of mercurial poisoning

James Addison Daniels, Carthage, Texas University of Tennessee Medical Department Nashville 1893, member of the State Medical Association of Texas, formerly mayor of Carthage, aged 65, died September 4 in a sanatorium at Shreveport, La.

Albert Martin Bleile, Columbus, Ohio, Starling Medical College Columbus 1876, member of the Ohio State Medical Association emeritus professor of physiology, Ohio State University College of Medicine, aged 77, died, August 16 of heart disease

John Charles Gunn ☉ Belleville, Ill. Washington University School of Medicine St. Louis 1900 served during the World War on the staff of St. Vincent's Hospital, and Home for the Aged aged 57, died suddenly, September 4 of heart disease

John Alexander Train, Chicago College of Physicians and Surgeons Chicago, 1891, member of the Illinois State Medical Society, aged 64 on the staff of St. Mary of Nazareth Hospital where he died, August 1, of cerebral hemorrhage

Archer Ward Jagger ☉ Flushing N. Y. University of the City of New York Medical Department 1893 fellow of the American College of Surgeons, for many years on the staff of the Flushing Hospital, aged 67, died August 29

George W. Green ☉ Dowagiac Mich., University of Michigan Ann Arbor 1905 fellow of the American College of Surgeons aged 62 on the staff of the Lee Memorial Hospital, where he died August 21 of gastric hemorrhage

Clifford Charles Kennedy, Norwood Ohio, Ohio-Miami Medical College of the University of Cincinnati 1910, served during the World War aged 48, died August 15, in the Christ Hospital Cincinnati, of myocarditis

Joseph White Williams, Paterson N. J. College of Physicians and Surgeons Medical Department of Columbia College New York, 1890, served during the World War, aged 67, died August 19, of heart disease

Harry S. Benham, Honeoye Falls N. Y., University of Buffalo School of Medicine, 1890, member of the Medical Society of the State of New York, aged 69, died, August 21, of cerebral hemorrhage and arteriosclerosis

William C. Anderson, Forest Miss., Memphis (Tenn.) Hospital Medical College, 1900 member of the Mississippi State Medical Association county health officer, aged 59, died August 23, of carcinoma of the lung

William Samuel Briggs, Dinwiddie, Va., Kentucky School of Medicine Louisville 1890, member of the Medical Society of Virginia aged 76, died August 6 in Petersburg (Va.) Hospital, of chronic interstitial nephritis

Wilber Emmett Fowler, Brookville, Kan. College of Physicians and Surgeons of Chicago 1884 member of the Kansas Medical Society aged 77 died, May 18 in St. John's Hospital, Sahna of diabetes mellitus

Walter H. Fuchs ☉ St. Louis Beaumont Hospital Medical College St. Louis 1891 formerly member of the city board of health aged 64, died August 16, in St. Luke's Hospital, of bronchopneumonia and peptic ulcer

Van Buren Knott, Victoria B. C. Canada Columbian University Medical Department Washington, D. C. 1893, veteran of the Spanish-American and World wars aged 61, died in July, of Buerger's disease

Mark Davis Lessard ☉ South San Francisco Calif. University of California Medical School 1923 aged 52 medical superintendent of the South San Francisco Hospital, where he died August 1, of heart disease

Edwin Brown Anderson, Chattanooga Tenn., Vanderbilt University School of Medicine Nashville 1896 member of the Tennessee State Medical Association aged 60 died August 28 of heart disease

Heydon Starrett, Forest Hills N. Y. College of Physicians and Surgeons Medical Department of Columbia College, 1889 aged 74 died August 16 of carcinoma of the rectum prostate and bladder

John Davis Gambill, Baltimore Johns Hopkins University School of Medicine Baltimore 1932 intern at the Johns Hopkins Hospital aged 26 was instantly killed August 8, in an automobile accident

Edmund Christie, Chicago McGill University Faculty of Medicine Montreal Que. Canada 1882 aged 72 died Sep-

tember 8, in the Hospital of St Anthony de Padua, of injuries received in a fall

Joseph Calvin Fahnestock, Piqua, Ohio, New York Homeopathic Medical College and Hospital, 1882, aged 75, died, August 19, in the Good Samaritan Hospital, Dayton, of heart disease

Maurice Benjamin Spector * Wrightsville Pa Temple University School of Medicine Philadelphia 1926, aged 34 died, July 27, in the York (Pa) Hospital of cerebral hemorrhage

Rodney Adren Wright * De Kalb, Ill, Hahnemann Medical College and Hospital Chicago 1913 on the staff of St Mary's Hospital, aged 47, died, August 24 in Prescott Ariz

Griffith Arthur Thomas, Detroit, Detroit College of Medicine 1900 for many years physician to the police department aged 61, died August 27, in the Harper Hospital, of hemiplegia

Edward Judson Burch, Carthage Mo Missouri Medical College, St Louis 1887 member of the Missouri State Medical Association aged 66 died August 3 of cerebral embolism

Theodore Shay Smith, Elton La Kentucky School of Medicine, Louisville, 1893 formerly parish coroner aged 74, died August 21, in St Patrick's Sanitarium Lake Charles

William Buermann * Newark, N J, Columbia University College of Physicians and Surgeons, New York 1896 aged 58, died, August 7, at his summer home in Awosting

John Elmer Meisenhelder * Hanover, Pa Johns Hopkins University School of Medicine Baltimore, 1902, on the staff of the Hanover General Hospital, aged 56 died, July 13

T G Brown, Gainesville Va (licensed Virginia by exemption in 1885) member of the Medical Society of Virginia, aged 76, died, August 3, of arteriosclerosis and hemiplegia

James W Temple, Rolla Mo, St Louis Medical College 1876, Civil War veteran formerly mayor of Eldon and member of the board of education, aged 84, died, August 14

Fred Stansbury, Becklev, W Va Loyola University School of Medicine, Chicago, 1919, aged 43 died August 10, in a local hospital, of hernia and a gallbladder infection

William F Walker, Elkhart, W Va, Kentucky School of Medicine Louisville, 1907 aged 57, died July 26, in a hospital at Charleston, of empyema of the gallbladder

John Gael Hathaway, New Bedford Mass, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895, aged 61 died, August 20

Frederick Hastings Shanks, San Francisco Jefferson Medical College of Philadelphia 1891 member of the California Medical Association aged 64, died, July 28

Thompson B Wright, Pasadena, Calif Columbus (Ohio) Medical College, 1886, veteran of the Spanish-American War, aged 69, died, August 22, of cerebral hemorrhage

Theodore Baker * Pittsburgh Johns Hopkins University School of Medicine, Baltimore 1904 member of the American Urological Association, aged 54, died August 11

Arthur B Adams, Omaha John A Creighton Medical College, Omaha, 1905, aged 55, died, August 16 in the Immanuel Hospital, of hypertensive heart disease

Dennis R Dupuis, Santa Monica Calif, Kentucky School of Medicine Louisville, 1902, aged 64 died July 21, of hypertension myocarditis and arteriosclerosis

Charles P Monro, De Ruyter N Y, College of Physicians and Surgeons, Baltimore, 1892 aged 66 died May 11, of cerebral embolism and coronary disease

Donald George Sinclair McKay, Madawaska, Ont, Canada, University of Toronto Faculty of Medicine, 1910, aged 47 was accidentally drowned, August 3

Glenn Wood, Pasadena Calif College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1899, aged 61 died, July 22

Jacob L Bowers, Little Mountain S C, University of Maryland School of Medicine Baltimore 1888, aged 72 died August 29 of cerebral hemorrhage

Edward Gabriel Gillis, Kensington, P E I McGill University Faculty of Medicine Montreal, Que 1899 aged 56 died August 7 of heart disease

Charles Barnes Smith Ilnfion Manit Canada University of Alberta Faculty of Medicine Edmonton 1928 aged 34 died May 19 of meningitis

Duke Keith, Los Angeles, University of Southern California College of Medicine, Los Angeles, 1904, aged 51, died, July 14 of chronic myocarditis

Gabriel Wolfgang Teschner, New York, College of Physicians and Surgeons, Medical Department of Columbia College, 1880, died July 14

John B Roth, Portland, Ore University of Oregon Medical School, Portland 1899, aged 68 died, July 22, of cardio-renal disease and cirrhosis

Walter H Cowgill, Philadelphia, Hahnemann Medical College of Philadelphia 1882, aged 73 died, September 1, of heart disease and uremia

William Gustav Freiday, Fort Lauderdale Fla, Jefferson Medical College of Philadelphia, 1889, aged 73, died, June 7 of cerebral thrombosis

Paschall Nathaniel Bowman, Sterling, Ill Barnes Medical College, St Louis 1899 aged 65, died, July 22 of nephritis myocarditis and arteriosclerosis

George Augustus Wood, San Francisco, Northwestern University Medical School, Chicago, 1905, aged 53, died August 18, of heart disease

James M Jenkins, Crenshaw, Miss, Memphis (Tenn) Hospital Medical College, 1904, aged 59, died, May 21 of cerebral hemorrhage

Heman J Whittier, Kansas City Mo, Eclectic Medical Institute Cincinnati, 1883 aged 77, died August 15, of hypostatic pneumonia

Willard A Curtis, Colorado Springs Colo Chicago Medical College, 1882 aged 80 died, August 19, in the Bethel General Hospital

Albert C Knapp, Cortland N Y, Syracuse University College of Medicine, 1896, aged 62, died, August 13, of malignant leukopenia

Julius Caesar Wise Kansas City, Mo Kansas City Homeopathic Medical College 1896, aged 89, died, July 28, of arteriosclerosis

Herbert Carl Martin, Hamilton, Ont, Canada University of Toronto Faculty of Medicine, 1915, aged 44, died, May 8, of myocarditis

Herbert Porter Stivers, Buechel Ky, Hospital College of Medicine, Louisville, 1896, aged 62 died, August 21, of heart disease

Eugene H Winkler, De Witt Ark Memphis (Tenn) Hospital Medical College 1891, aged 66 died in August, at Little Rock

Barton H Moss, Willow Okla (registered Oklahoma, by the state board of health, under the Act of 1908), aged 88, died July 20

Alexander Trautman, New York University of the City of New York Medical Department 1879, aged 83, died, August 19

Charles C Gidney, Plainview Texas, Louisville (Ky) Medical College 1892, bank president aged 66, died August 24

Emory Llewellyn Dial, Cleveland Western Reserve University Medical Department, Cleveland, 1898 aged 66, died August 25

Francis Asbury Bryant, Herrick, S D College of Physicians and Surgeons, Keokuk, Iowa, 1876, aged 81, died August 14

Arthur Jackson, Lockwood Mo Ensworth Medical College St Joseph, 1908, aged 48, died July 26, in Marshfield of uremia

Alphons M Kersten, Los Angeles Detroit Medical College 1885, aged 85, died, August 13, of myocarditis and arteriosclerosis

John F McGrath, Central Falls R I Illinois Medical College Chicago 1902 aged 54, died May 30, of angina pectoris

William H White, Amo Ind, Medical College of Indiana Indianapolis 1882 aged 77, died, August 25, of cardio-renal disease

Harbin Jacob Stevens, Medill, Mo Eclectic Medical Institute Cincinnati 1878 aged 85, died May 21, of senility

Bureau of Investigation

THE FEDERAL TRADE COMMISSION

More Nostrum Exploiters Brought to Time

The work of the Federal Trade Commission in helping to protect the public against misrepresentation or fraud in the medical field has been called attention to in this department of THE JOURNAL at various times. As has been previously pointed out, the Federal Trade Commission has powers in this field that are not possessed by the Food and Drug Administration that enforces the Food and Drugs Act. That Act as is well known, gives no control of fraudulent advertising of medicinal products unless such advertising appears on or in the trade package. The Federal Trade Commission has been given broad powers to investigate and take action in cases that involve or appear to involve unfair trade practices. False or fraudulent advertising is of course unfair competition. Where such unfair practices are proved the Commission may require the concern involved to sign a stipulation to the effect that the objectionable methods will be given up. In other cases the Commission may issue what is known as a 'Cease and Desist Order' in which the individual or company involved is ordered to cease and desist from practices that have been declared objectionable.

Recently (July 17 1933) the Commission reported that it had available for distribution statements of facts in a series of stipulation proceedings involving misleading advertising practices. We present here brief abstracts of such stipulations where they involve medical or quasi-medical products. These abstracts are supplemented in some instances by information from the files of the Bureau of Investigation of the American Medical Association.

E E Paddock—This man who operates from Kansas City, Mo., has for some years posed as a specialist in gallbladder disease. He recently signed a stipulation with the Federal Trade Commission to cease and desist against continuing false and misleading advertising. He specifically stipulated that he would cease representing in his advertisements that his treatment was an adequate one for gallstones, gallbladder or liver disorders; that it would strengthen or stimulate the organs so

that they would take care of gallstones; that it would induce a flow of healthy bile; that it would combat infection in the gallbladder; that his prescriptions embodied the combined knowledge of the medical profession; and other claims similarly preposterous. Paddock's activities have been

GALL
STONES and GALL BLADDER Irritations

Dr E E Paddock Desk 18 Kans. City Mo
(30 Yrs Experience in Chronic Diseases)

briefly referred to in THE JOURNAL and *Higia*. It was there pointed out that in addition to a gallstone cure he also seemed to have some connection with a concern calling itself the Lyle Chemical Company which put out a 'special prescription' for women called *Natura*. Those who answered his gallstone cure advertisement but failed to bite were later circularized by the Lyle Chemical Company. Paddock was born in 1867 holds a diploma from the Kansas City Medical College 1895 and a Missouri license of the same year.

Sargon and Sargon Pills—Sargon is a typical alcoholic patent medicine put out by G F Willis, Inc. of Atlanta, Ga. Willis was the former exploiter of Tantrac, a similar alcoholic nostrum. Sargon was declared misbranded under the Federal Food and Drugs Act because of false and fraudulent claims made for it. An abstract of the government's case against this nostrum appeared in this department of THE JOURNAL Jan. 3, 1931. Sargon Selt Mass Pills seem to be a complementary treatment that goes with Sargon and are apparently essen-

tially phenolphthalein. G F Willis, Inc. has recently filed a stipulation with the Federal Trade Commission agreeing to cease publishing false or misleading statements and specifically to cease claiming: (1) That Sargon is based upon a new or revolutionary formula; (2) that it accomplishes its results by new and amazing methods; (3) that it is the result of world-wide research; (4) that signed statements approving Sargon pour in from physicians and various other false and misleading claims. The concern also stipulated that it would cease misstating the official professional or educational standing of persons giving testimonials; would cease publishing testimonials that had been altered so as to change their meaning; and would also cease using testimonials that had been paid for unless the fact that they had been paid for was given publicly.

Natural Body Brace Company—This Salma Kan concern sells a body brace for which false and misleading claims have been made. It has recently filed a stipulation with the Commission agreeing to cease and desist from publishing false statements and specifically agrees to cease representing that the wearing of this body brace constitutes a competent treatment for such conditions as female weakness, constipation, unnatural thinness, colitis, kidney, bladder or liver trouble, heart ailments, lung trouble and various other conditions. It also agreed to cease claiming that by wearing its brace one could become 100 per cent efficient and that the braces were made to individual measure of the purchaser if they were not and similar unsupported claims.

Costs You Nothing to Try THE NATURAL BODY BRACE

IF NOT SATISFACTORY AFTER 30-DAY TRIAL

Overcomes Female Weakness—
Makes Walking and Work Easy
Develops erect, graceful figure longer, chest, bust, replaces and supports misplaced organs. Corrects stooping shoulders. Relieves backache, curvatures, nervousness, constipation after effects of flu. Thousands write the following:
"ENDS 10 YEARS OF SUFFERING"
"Before wearing your brace I could scarcely stand. I had suffered ten years with weak, troubled joints. I had suffered down pain, bladder troubles, nervousness, headache, constipation. Tried almost everything, but failed. I was a real old, weary suffering woman. Now what The Natural Body Brace has done for me, I cannot describe. I feel like a new woman. Made to your individual measure. Comfortable, easy to wear. Over 300,000 users."
Mail Coupon for free Illustrated Booklet,
"Health, Strength and Perfect Figure" and liberal trial proposition. (11)
THE NATURAL BODY BRACE CO.
Howard G. Clark, Pres.
306 Wash. Building, Salina, Kan.

Harris H Luntz—This person from Brooklyn, N. Y., under the trade name Beauty Research Corporation, sold a product called 'Formula Q' as an alleged treatment for wrinkles, sagging skin, age lines, etc. Harris H Luntz has been dealt with at some length in this department of THE JOURNAL in connection with the purchase of testimonials for the product. 'Flaxolyn' which Luntz purported to have discovered, 'Formula Q' has been sold under the claim that by its use a woman could get new beauty overnight; would be made to look ten years younger; would have every blemish cleared away. It was said to be a famous old secret lost for years, but rediscovered. The claim and similar ridiculous claims the Federal Trade Commission most conservatively declared to be incorrect, exaggerated and misleading. In a stipulation filed with the Commission the Luntz concern admits having made such misrepresentations but declares that it has discontinued the advertising of Formula Q and does not intend to resume such advertising and that the sale of the stuff will be limited to the filling of unsolicited orders.

Gaduette Company—This concern which hails from Battle Creek, Mich., is said to be a trade name used by Mary F. Poyer and Floyd R. Perkins. The Bureau of Investigation has no record of Mary F. Poyer but there is one Floyd R. Perkins listed in the files who some years ago was president of a 'deanness cure' concern known as the L. C. Grams Company which took over the business of a notorious quack, one Guy Chifford Powell (deceased). This same Floyd R. Perkins was at the same time listed as president of an advertising agency, the Charles H. Fuller Company, which was reported to have purchased Guy Chifford Powell's concern when that quack died and to have moved it from Peoria, Ill., to Chicago where the name was changed to the L. C. Grams Company. The Gaduette Company has been selling a product called Gaduette cream, that by their use one would be sure of weight and vitality to

a ripe old age Gaduettes were said to be a flesh and strength builder that would give you "vital energy" and make you look and feel like a million dollars." Now Mary E. Boyer and Floyd R. Perkins have signed a stipulation with the Federal Trade Commission admitting the exaggerated and misleading character of the claims made for Gaduettes and agreeing to cease and desist from circulating such false or misleading statements and specifically agreeing to cease claiming that Gaduettes will cause an increase in weight, strength, vitality, energy and health and that it will show an increase in weight and vitality and that it is both a flesh and a strength builder and that it is a competent treatment for masculine or feminine weaknesses as well as for rheumatism, neuralgia, bronchitis, goiter and gout.

Drysob Company—This was a trade name used by one S. S. Russell of St. Louis, Mo., who has been selling a preparation for the self-treatment of hemorrhoids. Some of the claims made by Russell have been that the oldest cases of piles are now as easy to end as a cold. He has declared that medical science found "Drysob" to be a new and better way to end piles than the use of surgery. He had also sold the stuff under the claim that "cases of long standing, no matter how stubborn or weakening, yield to Drysob's constant absorbing action." All of these claims and some others Russell has stipulated he will cease making.

Health Appliance Company—This Cleveland, Ohio, concern had been advertising an appliance and an astringent that was said to lift drooping chins "by shrinking released muscles and reducing flesh cells." The claim was made that by using

the device and the astringent one could "quickly bring back the fascination of that youthful chin-line of girlhood." The concern has stipulated with the Commission to cease publishing or circulating false or misleading statements and specifically to cease claiming that the astringent lotion aids or causes a shrinkage of muscles in the chin.

Conley Ointment Corporation—This Muncie, Ind., concern was incorporated under Indiana laws in 1928, with a retired merchant as president, a man connected with a local wood-bending company as vice-president and another man connected with a metal products concern as secretary and treasurer—experience in these fields presumably qualifying them to put on the market a medicine for the self-treatment of self-diagnosed human ailments. Their product was an alleged treatment for eczema and psoriasis which was sold under the claim that it was a quick, positive and permanent relief for both eczema and psoriasis. The company filed a stipulation with the Federal Trade Commission declaring that it had definitely discontinued the advertisements of its commodity and did not intend to resume such advertising in the future.

Clason Viscose Company—This Chicago concern according to the Federal Trade Commission, is the trade name of a common law trust operated by C. W. Cook, trustee. Presumably this is the Wilson Cook whose name has appeared in extensive advertising for the Viscose Company, which has claimed to cure varicose veins. The scheme, as it first originated, was dealt with in this department of THE JOURNAL, July 16, 1927. Now C. W. Cook has signed a stipulation with the Commission agreeing to cease and desist from continuing to make false and misleading statements regarding the treatment and he specifically agrees to cease claiming that the Viscose method will invariably stop or heal a large number of conditions

that in the past it has been alleged to stop or heal. He also has agreed to cease claiming that his treatment is uniformly successful and that there is nothing in the country so scientific and effective and that the healing of any and every varicose vein can be absolutely guaranteed, and various other specifically exaggerated and misleading claims.

The Southington Remedy Company—This concern which was a trade name for one A. C. Haysler, Jr., of Kansas City, Mo., has been engaged in the sale of an abortifacient "patent medicine" under the claim that it "safely relieves some of the longest, stubborn and unusual cases in three to five days." The Federal Trade Commission in quoting various claims stated that these claims implied that the Southington Remedy Company's nostrum would produce abortion and that it was a competent treatment for suppressed menstruation. Haysler has signed a stipulation agreeing to cease claiming either by inference or directly, that his preparation would cause abortion or that it was a competent treatment for the relief of suppressed menstruation or that stubborn and abnormal cases could be relieved by the use of it or that the use of the treatment would never cause disappointment and would relieve a woman from worry.

Leeithin Company—This was the trade name of one Raymond Doyle, of Long Island City, N. Y., who was engaged in selling "Leeithin Tablets" as an alleged aphrodisiac. As a sample of the claims under which the thing was sold, the following will suffice:

Men who have read the *Police Gazette* for years will be glad to learn that Leeithin is back again to help bring that show of pep and vigor which is the mark of strong healthy man.

Doyle has now filed a stipulation with the Commission stating that he has definitely discontinued the advertising of his tablets and does not intend to resume such advertising, and that in the future he will limit the sale of his tablets to the filling of unsolicited orders.

MidWest Products Company—This concern was a trade name used by W. D. Smith and Thomas A. Baden of Kalamazoo, Mich. From advertising matter in the files of the Bureau of Investigation it appears that there was also one

B. A. Smith connected with the concern. The company was engaged in selling a device called the "Prosager" as an alleged treatment for prostatic trouble. The device itself consisted of a rubber cylinder that was to be inserted into the rectum and to which attached by a tube, there was a rubber bulb. When the bulb was pressed air was forced into the rectal tube which would produce pressure through the rectum onto the prostate. The concern has filed a stipulation with the Commission agreeing to cease claiming, either by inference or otherwise, that the various symptoms that they have listed in their advertising literature are the result of derangements of the prostate gland and to cease, also, claiming that 65 per cent or any other per

centage of men past forty years of age have prostatic lesions, and finally, that they cease claiming that every physician concedes that massage is the only real treatment for prostatic trouble

Ulticur Company, Inc.—This Chicago outfit was earlier known as the 'Ulticur Company,' and sold a product that was alleged to be a cure for stomach ulcers. This was declared misbranded under the National Food and Drugs Act because of fraudulent therapeutic claims. The name 'Ulticur' in itself, being obviously fraudulent, the company changed it to 'Ulticur.' Now, under the newer name, having removed their fraudulent claims from the trade package (where they would come under the purview of the National Food and Drugs Act) to the newspapers, where they are apparently under no control, the Federal Trade Commission proceeded against them, with the result that the Ulticur Company, Inc. filed a stipulation agreeing to cease and desist from publishing false or misleading statements in general and specifically agreeing to cease representing (1) That Ulticur is a competent treatment for stomach or duodenal ulcers, and (2) that it is a cure for ulcers.

Johnston's Golden S O S Powder—This preparation was put out by the Johnston Chemical Company of Fort Bragg, Calif. and was sold under the claim that it was a competent treatment and an effective remedy for stomach ulcers, stomach pains and similar ailments. The company has filed a stipulation with the Commission declaring that it has definitely discontinued the advertising of 'Johnston's Golden S O S Powder' in interstate commerce and that the sale of the commodity beyond the boundaries of the State of California will be limited to the filling of unsolicited orders.

Correspondence

DIABETES AND BLOOD TRANSFUSION

To the Editor—I have recently had several striking experiences in doing Aschheim-Zondek tests on rabbits, and in doing one blood transfusion with a diabetic donor. So far as I know there are no published reports of similar experiences and my reason for recording them is to sound a warning to those doing blood transfusions, that they may avoid similar and possibly fatal accidents.

About one year ago I had occasion to perform an Aschheim test for suspected pregnancy. I used the technic that I had previously used in many instances, by injecting about 8 cc of freshly voided urine into the marginal vein in the ear of a rabbit. On this occasion after a little more than half of the urine had been injected the rabbit was taken with a convulsive seizure and was dead immediately. I secured a second specimen of urine this time doing a chemical analysis and found that the patient was moderately diabetic as shown by Benedict's solution test. I repeated the Aschheim test with this urine and had the same experience with this rabbit.

A short time after this I had occasion to do a blood transfusion on a 3 months old baby. The father's blood was typed and cross agglutinated and showed no incompatibility. He was known however to be diabetic. He was under treatment and his urine was free of sugar and ketone bodies. After about 150 cc of the blood had been given to the baby intravenously the child went into a sudden collapse and was pulseless, breathless and livid. After strenuous efforts at resuscitation the child revived but passed a rather stormy three or four days subsequently. The examination of the urine and blood showed nothing to indicate that the reaction had been due to blood incompatibility. My experiences with the rabbits previously made me feel that there was a relationship between the accidents to the rabbits and the symptoms shown by the baby.

Just today I had a similar experience in doing an Aschheim test on a patient who is mildly diabetic as shown by a positive

Benedict test and also positive acetone. I have had considerable experience with the Aschheim test over a period of years and at no time have I had any reactions in the rabbits except in these cases of diabetes.

Unless there have been previous reports of a similar nature which are unknown to me, or until further work can be done along this line, I believe it would be wise for those doing blood transfusions to eliminate known diabetic patients as donors, because I believe it is possible that some of the untoward symptoms and possibly deaths following transfusion in the past may have been due to the use of diabetic donors.

E C BAUMGARTEN, M.D., Detroit

SALE OF PHYSICIANS' SAMPLES

To the Editor—May I call your attention to a possible new 'racket', certainly it was brand new for me. A man came into my office very well dressed, and wanted to buy any 'physicians' samples' I had on hand. I told him I had none on hand. He then wanted to know if he might call at some future time for any samples I might have. I didn't invite him to do so, but I did inquire as to what possible use he might have for them and he said that there was a sale for them.

Pharmaceutical manufacturers would hardly care to have the samples which they have left in the hands of physicians disposed of in this way. There must be some angle to all this which is not apparent on the surface. If this is a practice carried out on a wide scale in numerous cities, I can see that it might definitely affect manufacturers.

WALTER C. ALLEN, M.D., Rochester, N. Y.

"ACUTE EPIDEMIC POLIOMYELITIS COMPLICATING PREGNANCY"

To the Editor—Drs. M. Bernard Brahdly and Maurice Lenarsky described in THE JOURNAL, July 15, three new observations of acute epidemic poliomyelitis complicating pregnancy. Justly, it seems, they assume that many of these cases remain unreported though undeniably a larger number of reported cases would greatly aid the obstetrician in solving various problems presented by a pregnant woman suddenly exhibiting the symptoms of poliomyelitis. This valid argument induces me to place another case on record.

Mrs. E. B., when seen, Jan. 5, 1925, was 18 years old and had been married six months. She last menstruated at the expected time Nov. 16, 1924. A diagnosis of normal intra-uterine pregnancy was made. The physical condition was normal in every respect. The time of expected delivery was August 23. Pregnancy progressed normally.

June 30 general malaise developed and the patient's temperature was 100. Next day the temperature varied between 99.5 and 100. She complained of aching over her entire body. All the muscles were tender. The question of poliomyelitis was considered but there were no signs of paralysis. The following day (July 2) the muscle tenderness was most marked in the right leg. Late in the afternoon the patient was unable to move it. The diagnosis of acute poliomyelitis was confirmed by a neurologist.

Gradually all the muscles of the right lower extremity became involved as well as some muscles of the right arm and of the face. Further progress was typical. The paralytic symptoms gradually receded, only a few muscles of the right leg remained paralyzed.

Feeling again entirely well the patient went into labor approximately the expected time August 24. Labor was fairly easy and entirely normal. The patient was delivered by means of perineal forceps of a male infant weighing 3265 Gm. per-

feetly normal. The puerperium was disturbed by a perinectal abscess.

At present (September 1) the patient is in the third month of her second pregnancy. Outside of a slight limp she exhibits no symptoms of the disease. The child, now 8 years old is physically and mentally normal.

HUGO EHRLICHST, M.D., St. Louis

THE CLINICAL MANIFESTATIONS OF SILICOSIS

To the Editor—On reading "The Clinical Manifestations of Silicosis" by Dr. R. R. Sayers and the discussion in *THE JOURNAL* August 19, it occurred to me that although the author stressed shortness of breath as the cardinal symptom and decreased chest expansion as the cardinal sign of the condition no mention was made of the obvious importance of vital capacity readings. It is well known that measurements of chest expansion are unreliable. With the spirometer the vital capacity of these patients could be quickly and reliably checked.

KENNETH A. OWEN, M.D., Charleston, W. Va.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

CONGENITAL SYPHILIS WITHOUT OBVIOUS SIGNS

To the Editor—A woman aged 32 married but separated from her husband with a clinical picture of syphilitic aortitis confirmed by a four plus Wassermann and a two plus Kahn reaction Dec. 7, 1932 was given strong mercury rubs one-half drachm (2 Gm.) nightly for two weeks when they were discontinued because of diarrhea which cleared after one week without the rubs. At this time bismuth sodium tartrate was given twice weekly for only six injections (the last one January 16). This was discontinued because of apparent bismuth or mercurial stomatitis, diarrhea and albumin in the urine which was not present before. The patient went down grade for the next three weeks from 170 pounds (77 kg.) to 135 pounds (61 kg.). By March 9 she was well enough to be out again and a Wassermann test taken then was negative as was the Kahn test. An examination five days later gave the Wassermann reaction as one plus and the Kahn reaction negative. I have started her on the second series of bismuth using iodobismutol and have had no reactions from the first three injections. Her son is 13 years old. He was born with eczema but other than that which cleared in a short time he has been perfectly healthy and is now in the eighth grade and of average status. His Wassermann reaction is four plus and Kahn reaction four plus but there are no signs of congenital syphilis present. The reflexes are normal, there are no Hutchinson teeth, keratitis nor leukoplakia. The sense position is normal and memory is normal. The only sign I can find is that in test sentences he has difficulty in saying "Methodist Episcopal." His father is said to be syphilitic although I have not seen him. The boy's general physical examination is negative.

The questions I cannot answer are: 1. What causes the severe reaction with so little medication of the mother and a negative Wassermann reaction if syphilis has been present a minimum of thirteen years? 2. Is the boy syphilitic? If so why are there no signs after thirteen years? 3. What further treatment should the mother have and what treatment should the boy have? This is the only pregnancy the mother has had. She gives no history of a primary or secondary stage. Please omit name and address.

M. D. Ohio

ANSWER—1. The severe mercurial reaction here described in the woman as manifested by diarrhea, stomatitis and albuminuria indicates a marked sensitivity to mercury. An individual sensitivity to any drug, foodstuff or foreign protein is a constitutional factor of any given organism, and the degree of reaction in any specific case can never be predicted. The idiosyncrasy may be individual or familial. The reaction of cats to morphine is a time-honored example of the different reaction which any drug may have on a certain species of animal. As long as there was no reaction from the first three injections of iodobismutol it would be well to continue this drug. The serum reactions cannot be used as a definitive index to the extent or degree of a syphilitic process. This patient has clinical evidence of a syphilitic arteritis of the aorta and deserves the benefit of a complete and thorough course of antisyphilitic treatment no matter what the laboratory test may show.

2. The boy is said to have no signs of congenital syphilis with the exception of difficulty in saying "Methodist Episcopal" and four plus blood Wassermann and Kahn tests. Neurosyphilis

may occur in syphilis hereditaria tarda without other typical signs of congenital syphilis and with slight or no demonstrable signs of nervous system involvement. Tabes dorsalis and dementia paralytica are not common manifestations of congenital syphilis but are known to occur.

A spinal fluid examination would be strongly indicated in this case. If serologic tests on the spinal fluid and colloidal gold reactions are positive strong evidence for neurosyphilis of congenital origin would be obtained. The history in the mother and father also substantiates such a diagnosis. Asymptomatic neurosyphilis is not an infrequent manifestation of congenital syphilis. In a large series of congenital syphilitic children only one third of the number with pathologic cerebrospinal fluid showed demonstrable clinical evidence of neurosyphilis.

3. As has been indicated a thorough and complete course of antisyphilitic treatment with iodobismutol should be given the mother. In the case of the boy, if the spinal fluid is found to be positive an intensive course of antisyphilitic treatment would be imperative.

The treatment for the boy may consist in the use of an arsenical intravenously, intramuscularly or orally. The arsenical may be alternated with a course of compounds of mercury, bismuth or iodine though a definite rest period between arsenical courses is absolutely indicated.

The dosage in children for intravenous neoarsphenamine is 15 mg. per kilogram of body weight for intramuscular sulpharsphenamine the dosage is 20 mg. per kilogram of body weight and the oral dosage of acetarsone for children is an initial dose of 5 mg. per kilogram of body weight daily, increasing to 20 mg. The arsenical courses may be given for periods of from six to nine weeks followed by a rest period of from two to three months. Serologic examinations of the blood and the spinal fluid should be made at the beginning or end of each course and the blood and urine should be carefully controlled. Arsenical reactions demand immediate cessation of treatment. In case of a severe arsenical reaction, iodobismutol might be used in the proper dosage for a child.

PALLIATIVE TREATMENT FOR RECTAL STRICTURE IN AGED

To the Editor—What palliative treatment is indicated for rectal stricture in a woman of 78 unable to undertake the radical treatment? She has hemorrhoids too. Constipation is controlled by mild laxatives. I have used suppositories with little success. Please omit name.

M. D. Ohio

ANSWER—The only palliative treatment for stricture of the rectum in a woman 78 years of age unable to undertake radical treatment would be to obtain a rectal dilator such as a Hegar metal dilator, of exactly the size of the stricture so that this may be used two or three times a week to prevent the stricture from still further contracting down. Liquid petrolatum, a laxative diet and mild laxatives of course may also be used. In the event that the stricture is in such a position that it cannot be maintained in its present position by dilation and the opening is so small that elimination is impossible, a colostomy could be done under local anesthesia.

TREATMENT OF SYPHILIS

To the Editor—A woman patient of mine aged 25 contracted syphilis six years ago. Until 1930 she had received at intervals short courses of arsenicals intravenously. She received no treatment from that time until February 1933 when I saw her at which time she had a 4+ Wassermann reaction. She had a similar reaction of the spinal fluid a colloidal gold curve of no particular significance and an increase in globulin. No cell count was made. The patient was given eight injections of bismuth salicylate intramuscularly at weekly intervals followed by eight intravenous injections of 0.6 Gm. of neoarsphenamine at the same time interval. Without any rest period she was started on another series of bismuth injections. I have given her four injections of her second bismuth series and find a 3+ albumin in the urine. Microscopic examination is negative. The patient has also been taking potassium iodide regularly. In view of the urinary finding what type of treatment should I employ? Her blood Wassermann reaction now being reported as 3+? When should treatment be employed toward the syphilis of the nervous system? Do bismuth compounds have an effect on the kidney? Please omit name.

M. D. New York

ANSWER—In view of the albuminuria, it would appear to be safer to discontinue all treatment for a time. If after a rest period of several weeks the albumin has disappeared, treatment could be commenced cautiously, the urine being watched at frequent intervals. There is no reason why treatment for the neurosyphilis should not be given at once. A course of trypanarsamide or intravenous acetarsone may be administered provided the eye examination is satisfactory. Even malarial or fever therapy might be considered. Bismuth compounds not infrequently cause albuminuria, more especially in cases in

which stomatitis develops. Bismuth nephritis is well known and was often reported by the early French workers, who gave large doses of bismuth salts and employed them by the intravenous route. Schamberg and Wright state that although experimentally bismuth appears to be exceedingly injurious to the kidney, in actual practice it has not proved to be so but has proved less harmful than mercury.

DIAGNOSIS OF TYPHOID

To the Editor—I have been attending a woman aged 38 who was taken ill August 6 with nausea and vomiting. She vomited every day until August 11 when I was called for the first time to see her. I found her apathetic with a fever of 102 and a pulse of 100. Her chest was clear throughout her illness; there was slight generalized abdominal tenderness but no constipation nor diarrhea. The fever continued and for several days varied between 103.5 and 104 F. For one day her pulse was definitely dicrotic. The white cell count was 3,550. August 16 a differential count was not done. Her spleen could not be palpated but she is very obese. There was no suggestion of rose spots. A blood culture August 16 showed no growth but a Widal test the same day was strongly positive for B typhosus and negative for paratyphosus A and B and for *Alcaligenes abortus*. Six fecal cultures have been taken and have been negative throughout. The fever continued for two and one-half weeks and descended by lysis. She is now convalescing nicely. The patient lives on a dairy farm on which occurred three and one-half years ago three definite cases of typhoid proved by fecal culture and Widal tests. At that time this woman had three injections of typhoid paratyphosus A and B mixed vaccine as a prophylactic. 1. Is there any reliable method by which the agglutination resulting from preventive inoculation can be differentiated from that of clinical typhoid? 2. If this case were not true typhoid would not the paratyphosus A and B agglutinations be correspondingly positive? 3. Can clinical typhoid be assumed in this case without any demonstration of bacilli in blood, feces or urine? Please omit name. M D New York

ANSWER—1. After the fever has subsided agglutinins due to inoculation cannot be distinguished from agglutinins due to infection. A more or less gradual rise in the specific typhoid agglutinin titer during the course of the fever would indicate typhoid infection.

2. As the paratyphoid agglutinins are different from the typhoid there is no certainty that both paratyphoid and typhoid agglutinins would all be present three and a half years after the injection of mixed vaccine.

3. The facts and circumstances of the case appear to warrant the conclusion that the patient had a mild attack of typhoid.

APPENDICITIS AND DUODENAL ULCER

To the Editor—A man aged 32 has been getting treatment for duodenal ulcer for the past three years. He has two or three attacks yearly which keep him from his occupation of light labor for about six to eight weeks each time. Roentgen examination shows duodenal ulcer and a subacute appendicitis (thirteen years ago he had several appendiceal attacks). The patient has had teeth but is otherwise normal. Would you advise in view of the repeated failures from dietary procedure, appendectomy alone or appendectomy together with an attempt at cauterization of the ulcer or gastroenterostomy or any other procedure you consider better? J H Boyd M D Trenton N J

ANSWER—Under the circumstances it would seem the better part of wisdom not only to remove the appendix but to attack the ulcer surgically. If conditions permit a pyloroplasty after the method of Judd could be carried out or a posterior gastroenterostomy made with excision of the lesion if it involves the anterior duodenal wall. It is also essential that the diseased teeth be removed in stages and that for at least a year the patient carry out the usual dietetic precautions, use tobacco and alcoholic drinks in moderation if at all, avoid physical and nervous fatigue and get at least eight hours of sleep each night.

SUSCEPTIBILITY TO YELLOW FEVER—IMMUNIZATION AGAINST ROCKY MOUNTAIN FEVER

To the Editor—How can I determine whether a man is susceptible to yellow fever? How can he be immunized against yellow fever? How can a man be immunized against Rocky Mountain fever? Please write me fully. Please omit name. M D Missouri

ANSWER—Susceptibility to yellow fever may be determined by the mouse protection test of Sawyer and Lloyd. In this test anesthetized mice are first injected intracerebrally with sterile starch solution (0.03 cc of a 2 per cent solution); this procedure is for the purpose of localizing the virus in the brain. Immediately following this each mouse is injected intraperitoneally with a mixture of 0.2 cc of a 10 per cent suspension of virus-containing mouse brain and 0.4 cc of the serum to be tested. Six mice are treated in this way and also two control groups of six mice each: one control group with immune serum, one with normal serum. If five mice in the test group survive and the controls are successful the serum is considered pro-

tective, i. e. the individual is immune. If five out of the six die the serum is considered to have no protective value. Results deviating from these figures are regarded as inconclusive.

Immunization against yellow fever, as carried out by Sawyer and others in the laboratories of the International Health Division of the Rockefeller Foundation, consists in the subcutaneous injection of human immune serum of tested potency followed immediately by the injection of a dried mixture of living yellow fever virus fixed for mice and human immune sera. The immunity obtained in this way is comparable to that reached as the result of a natural attack of yellow fever. Details may be found in an article by Sawyer, Kitchen and Lloyd (*J Exper Med* 55:945 [June] 1932).

A vaccine against Rocky Mountain spotted fever has been prepared by Spencer from the ground viscera of infected ticks. Two or three inoculations of the vaccine give some degree of protection and apparently lessen the severity of infection when it does occur. The protective effect is not permanent but may last for several months. Information about the availability of this vaccine may be obtained from the U S Public Health Service.

USE OF SODIUM AMYTAL IN OBSTETRICS

To the Editor—In Queries and Minor Notes (*THE JOURNAL* August 5, p. 468) an answer is given to a question for information regarding the use of sodium amytal in obstetrics. The answer reads that frequent narcotization of babies has been reported following the use of this drug. I should like to have the references to such opinions since in my experience with about a thousand obstetric patients to whom sodium amytal was given I have failed to observe even once that the babies were depressed as a result of the drug.

SAMUEL M DODER, M D Washington D C

ANSWER—Shir and Daichman (*Am J Obst & Gynec* 24:115 [Jul] 1932) report their experience with sodium amytal in 100 cases. There were no ill effects on the baby when small doses were used but no appreciable analgesia was obtained when the small amounts were employed. Of fifty-one cases in which the initial dose varied from 9 to 15 grains (0.6 to 1 Gm.) eleven babies were narcotized at birth. After pointing out the merits of sodium amytal the authors conclude that these advantages are greatly outweighed by the frequent occurrence of marked restlessness, an increase in the number of instrumental deliveries and frequently narcotized babies.

J J Swenson (*Minnesota Med* 13:868 [Dec] 1930) reports his experience with sodium amytal and says: "One third of the babies are somewhat apneic at birth apparently due to a torpidity of the respiratory center induced by the drug and require stimulation to establish respiration."

BREAST PAIN DURING MENSTRUATION

To the Editor—A woman of approximately 40 years, somewhat inclined to obesity and with large pendulous breasts complains of pain in both breasts for a period of from seven to ten days before each menstrual period. This pain is severe enough to be quite distressing. The breasts do not show any marked swelling at this time. Kindly suggest what mode of treatment would be most efficient for relieving the pain. Could you suggest any exercises or treatment that would tend to lessen the size of the breasts other than the reduction of the general body weight? Please omit name. M D Missouri

ANSWER—Breast pain associated with menstruation appears to have become much more frequent during recent years than formerly. The explanation is not evident, the lessened adiposity of modern women, lack of exercise due to more automobile riding and the nervous strain of present day life are possible etiologic factors. In some cases the breasts are 'sympathetically' disturbed because of an ovarian growth or other genital disturbance. A pelvic examination is indicated in all these cases. As regards treatment, comfortable clothing which does not exert undue pressure and employment of a supporting brassiere that lifts but does not press are essential. Acetilsalicylic acid gives comfort to some patients. Those who are nervous are helped by an alcoholic solution of phenobarbital or other sedatives. There is no specific treatment.

LEAD PIPING AND LEAD POISONING

To the Editor—I have a family that presents general symptoms of chronic lead poisoning. I am wondering whether the lead piping that connects the water service to this house could be responsible for any of the symptoms of chronic lead poisoning. I will appreciate any enlightenment on the subject. GEORGE A HOGAN, M D Birmingham Ala

ANSWER—In 1928 Wright and his associates (*J Indust Hyg* 10:214 [Sept] 1928) reported on a survey embracing 102 lead conducted water supplies. The study embraced chemical and clinical observations. All waters analyzed contained lead. The lead content was most intimately related to the

carbon dioxide content. There was no apparent relation between the length of pipe and the lead content. Of ninety sources used by the persons studied, thirty-five caused poisoning as determined by certain criteria. Of 253 exposed persons, 63, or 24.9 per cent, were poisoned. Poisoning occurred among fourteen persons ingesting as little as 0.1 mg. of lead daily, over an average period of eight and one fourth years.

The incidence of poisoning was distinctly lower in children under 10 years of age than among children from 10 to 20 years old or among adults, and was greater among adults than among children under 20. The duration of exposure, except for short periods, was not significant in its relation to the incidence of poisoning. The incidence of poisoning was quite uniform among those ingesting varying amounts less than 15 mg. daily but was much greater as this amount was exceeded.

IODIZED OIL FOR PNEUMOGRAPHY

To the Editor—Several years ago in answering a communication from Dr. J. D. Riley of the State Sanatorium, Booneville, Ark., you stated that a bronchogram with iodized poppy seed oil was contraindicated in pulmonary tuberculosis. Since that time many hundreds of bronchograms have been made in patients having the exudative and fibrocaseous type of pulmonary tuberculosis with positive sputum and I should be glad if you would let me know if your attitude in regard to this procedure has changed.

B. L. CRUICKSHANK, MD, Paterson, N. J.

ANSWER—This procedure, utilizing such agents as iodized poppy seed oil, is practically harmless, with the exception of those instances in which pulmonary hemorrhage may be present and the oil may aid in producing a blockage of a bronchus with a consequent atelectasis or in which the production of such a bronchial obstruction in the presence of large amounts of sputum may prevent proper drainage and cause symptoms of absorption to occur. The earlier ideas contraindicating the use of iodized oil were based on erroneous thoughts concerning the action of iodine in tuberculosis. Pure iodine in solution does not affect tuberculous tissue adversely when utilized in dilution as is found in substances such as iodized oil or when taken by mouth therapeutically. It is only the alkaline iodide salts such as potassium and sodium which, by causing dissolution of necrotic tuberculous tissue and increasing secretions from the bronchial mucosa, allows a "spilling over" of the new admixture of such secretions and necrotic tissue containing large numbers of tubercle bacilli, permitting of endogenous reinfection with its consequent extension of the pulmonary disease.

The presence of pulmonary tuberculosis, when one wishes the additional aid of pneumography in outlining such conditions as bronchiectasis or bronchogenic carcinoma obstructing the lumen of a bronchus or possible bronchial fistula does not prevent its use. One should observe the ordinary precautions of technique necessary in a tuberculous individual.

SPONTANEOUS RUPTURE OF VEINS

To the Editor—A young white woman is having a series of spontaneous venous ruptures both superficial and deep. The veins are not varicose and do not seem hard or brittle. Physical examination is essentially negative. The urine is normal, the coagulation time is normal, the blood picture is normal, the blood sugar is normal. The family history is irrelevant with the exception of diabetes in the father. A rupture of a large vein in the leg resulted in sufficient venous stasis to necessitate rest in bed over a period of eight weeks before enough circulation was reestablished to permit walking. I would appreciate comments on this case as to prognosis and treatment and also would appreciate a speedy reply. Please omit name.

M. D. New York

ANSWER—In cases of spontaneous venous hemorrhage, various types of hemorrhagic purpura, caused by infection, avitaminosis or thrombopenia, must be first excluded. Besides the coagulation time, which is normal in purpura, the bleeding time, clot retractility, platelet count and constriction test are most helpful. These tests need little equipment and may give important information. In a certain group of young women all these tests are negative, the blood calcium is normal and yet there is a marked tendency to bruise easily because of an increased fragility of the vessel wall. This is often hereditary. It is not surprising that endocrine products, particularly parathyroid, ovarian and pituitary extracts, have been indiscriminately used in these vague and poorly understood disorders. Large doses of calcium gluconate, from 2 to 4 Gm. (30 to 60 grains) three times a day seem to cement the vessel wall against such injuries and certainly influence the edema favorably.

One must think also of rare neurotrophic petechial hemorrhages, which accompany cord lesions. An injury no matter how trivial it may seem may be the causative factor if the vessels rupture easily. It is not clear why the correspondent makes the diagnosis of a rupture of deep veins. In all probability the saphenous area and perhaps some muscle veins are

affected. As a final possibility, the rare syndrome of endothelioplasmic dystrophy of Weill and Block is suggested which is characterized by a nonretractile clot, capillary hemorrhages and a seemingly aseptic thrombosis in the larger veins. Consultation with a man specially interested in this field might clarify the diagnosis, prognosis and treatment.

MOON BLINDNESS IN HORSES

To the Editor—Because I am an ophthalmologist a personal friend has asked me to see a valuable saddle horse suffering from so-called moon blindness. I have no idea what moon blindness may mean in animals but I take it that this is a form of interstitial keratitis because the objective symptoms seem to be of that type. The veterinarian is giving this horse injections of neosphenamine. Can you tell me or refer me to a source of information regarding this condition?

WALTER STEVENSON, MD, Quincy, Ill.

ANSWER—Moon blindness in horses corresponds fairly closely to myopia in the human being and can best be treated along similar lines. A few years ago, Rankin investigated a series of cases of moon blindness in one of the racing stables of Kentucky. Injections of whole milk were used beginning with 1 cc. and not exceeding 2 cc., given on alternate days. Atropine ointment was used in the eyes. The owners reported that all the horses treated were improved and that some of them recovered vision entirely. It was the most effective treatment that had ever been administered in their stables. Care must be taken with the use of foreign protein injections in horses, for they are extremely susceptible to a dose that would not have any influence on a child.

UNILATERAL ATROPHY OF BREAST

To the Editor—Will you kindly give me any information you can regarding unilateral atrophy of the female breasts? The case in mind concerns a woman, aged 23, who otherwise appears to be in perfect health and has had no pregnancies. The menstrual periods are rather scanty and irregular and are frequently missed. The right breast is about 25 per cent smaller than the left and considerably more pendulous, suggesting atrophy of the glandular structures and fatty tissues. Any information you can give me regarding the cause and treatment of this condition will be appreciated. Please omit name.

M. D. Wisconsin

ANSWER—Little is known about unilateral atrophy of the female breast. As a rule, unilateral atrophy is an expression of atrophy of the breast occur after pregnancy, and for some reason or other there are usually one or more abscesses in one or both breasts. There are cases of atrophy of the breast associated with malnutrition. Atrophy of the breast is rare except senile atrophy which is always present when people are underweight and atrophy following multiple abscesses of the breast during pregnancy and lactation. This unilateral atrophy in a girl of 23 who has never had children is most unusual.

TREATMENT OF ENDOCRINE OBESITY

To the Editor—A woman, aged 44, was operated on for inward goiter about two months ago by a competent surgeon. The patient felt better for a while but now feels as bad as she did before the operation. She gets out of breath and tires easily. She gained 15 pounds (6.8 kg.) of adipose tissue below the ribs and above the umbilicus. This flesh looks like an automobile tire hung about her. On the rest of the body the fat does not show. Her weight now is 158 pounds (71.7 kg.) while formerly she always weighed 145 pounds (65.8 kg.). The pulse is 90 and the basal metabolic rate +21 per cent. The history otherwise is negative except for a fibroid tumor in the muscle of the uterus. She has had this tumor for several months. The distress is from the accumulation of fat around the lower part of the ribs, pressing on the heart especially when she is bending down. Will this fat gradually leave as the body becomes adjusted? What can be done for her for temporary or permanent relief? Any suggestions will be gratefully received. Please omit name and address.

M. D. Iowa

ANSWER—It is unusual to have such a local fat deposit although it is by no means rare for thyroidectomy to result in considerable deposits of fat. The localization of the fat areas around the girdle suggests some pituitary disturbance. There is no reason to anticipate that the fat will leave unless some type of endocrine therapy is used. The basal metabolic rate of +21 per cent does not warrant the use of much thyroid, although it can be employed in small doses under careful observation. A dose of 0.03 Gm. of thyroid extract a day is recommended as a start. It might also be wise to add injections of solution of pituitary, 1 cc. every other day. This, like the thyroid, must be considered in the nature of experimental therapy.

In addition to the specific endocrine treatment, massage of the parts involved and a low caloric diet will be necessary to attain any results.

EFFECTS OF FACE CREAMS ON SKIN

To the Editor—Will you please state what effect face creams have on the skin? Do they have a tendency to prevent wrinkles? Please omit name

M D Missouri

ANSWER—Face creams supply fat when nature fails to do so. The fat is an important ingredient of the skin keeping the horny layer soft, flexible and water tight and forming over it a thin, protective film. The lack of fat predisposes to sunburn or windburn in summer and chapping in winter, both of which lead to earlier aging of the skin. They can be prevented by the use of cold cream and other means of protection of the skin. Owners of blonde skins that do not tan should begin taking precautions against irritation early in life, for only then can effective work in this line be done.

Face creams, used for cleansing dry irritable skins, also prevent irritation by soap which would be necessary were the cream not available. Wrinkles are one sign of aging of the skin, and anything that will prevent these irritations helps to postpone the onset of wrinkles.

EFFECTS OF TEAR GAS ON EYE

To the Editor—Will tear gas shot directly into the eyes by the small cartridges carried by police officers cause blindness or severe enough injury to the cornea to affect the vision?

CLARENCE MINNICK M D Cambridge, Neb

ANSWER—That depends on the distance between the eye and the pistol. If the distance is short, possibly less than 2 or 3 feet, the chloro-acetophenone is still in liquid form and can produce severe chemical injury to the cornea that will undoubtedly result in marked loss of vision or even complete loss of the eye. But if the liquid has had an opportunity to become converted into the gaseous form, practically no danger is to be anticipated. Of course there is a severe reaction of the eye to the irritation of the gaseous chloro-acetophenone, hence the name tear gas, but the danger of permanent injury is slight. Even if the liquid form reaches the eye the McNally sodium sulphite treatment can avert serious damage, if applied early and thoroughly.

ARTHROPLASTY OF HIP JOINT

To the Editor—Kindly give some information regarding Murphy's operation for arthrodesis of the hip joint. I should like to know the general percentages of success, what is the usual range of motion expected and just how long before a person can resume ordinary walking provided the operation is a success and there are no complications. Is there usually more or less continued pain after the joint is made useful? The books that I have give the operative technique in detail but too little explanation of the after effects. Your information would be appreciated. Please omit name

M D Florida

ANSWER—Arthroplasty as performed by Dr John B. Murphy from 1903 to 1916 has been considerably modified in that a free transplant is now being used instead of the pedicle flap transplant as outlined by him. Otherwise the essentials of the arthroplasty remain the same. The examination of hip joints on which operation was performed during 1908 to 1918 disclosed that satisfactory results were obtained in about 60 per cent of the cases. Since the modified operation has been used, the proportion of satisfactory results has increased to about 75 per cent. One noted orthopedic surgeon reports as high as 80 per cent good results in operation on the hip. The usual range of motion hoped for in this operation is that the patient may comfortably sit erect and that ordinary walking should be resumed in approximately eight weeks. The complications one occasionally sees are those of infection and a return of the stiffening of the joint. In cases in which the joint has been well formed and no infection has ensued, the amount of pain is negligible.

TREATMENT OF SPINAL CORD LESIONS IN PERNICIOUS ANEMIA

To the Editor—I have a patient with pernicious anemia. She has also a posterolateral sclerosis which is due to her anemia. Under liver dilute hydrochloric acid and iron ammonium citrate she has responded well. The condition of her hands does not improve, she has numbness and loss of touch sensation as well as a partial paralysis of the extensor and flexor groups. Can you tell me of anything that might improve this condition? Please omit name

M D New York

ANSWER—The treatment of the spinal cord lesions that are associated with pernicious anemia now constitutes the major problem in the management of the disease, as they show much less improvement following liver or stomach therapy than does the anemia. The first principle in the treatment is to give liver, liver extract or desiccated hog stomach in adequate amounts until the hemoglobin is between 85 and 100 per cent

and the red blood cell count is between 45 and 5 per cubic millimeter. It is important that the blood should be brought to an entirely normal condition and maintained there by appropriate therapy. In some cases it may be necessary to administer liver extract intramuscularly or intravenously in order to accomplish this.

Recently satisfactory improvement has been reported when fresh ox brain has been given in addition to the liver or stomach medication. As much as a pound of ox brain may be given daily, if it is ground in the finest meat grinder and one-fourth pound mixed with a glass of grape juice. This amount may be administered four times daily.

The patients should be urged to exercise the arms and legs but cautioned to avoid excessive fatigue.

AMEBIASIS

To the Editor—Is it possible for a man to have amebic dysentery and not be able to demonstrate amebas in the stool? Please omit name and address

M D Minnesota

ANSWER—Before the development of modern cultural methods it was not infrequent to find persons harboring *Endamoeba histolytica* in whose stools it was difficult to demonstrate amebas by microscopic examination for extended periods. These negative periods still occur but are much rarer with cultural methods. Some clinicians who believe in various generalized symptoms of amebiasis have described more or less obscure symptoms in these periods, but it would be unlikely to have a patient suffering from frank dysentery and not to be able to demonstrate amebas by culture for any length of time.

MALARIA IN FLORIDA

To the Editor—What are the dangerous months of the year for infection with malaria in St. Petersburg, Fla.? Kindly omit name

M D, Ohio

ANSWER—It would be possible to become infected with malaria in St. Petersburg, Fla. during any of the time between May and November, depending on the particular conditions of rainfall and temperature for a particular year. Although Mayne found infected *Anopheles quadrimaculatus* mosquitoes as early as May 15 in Bolivar and Washington counties, Miss., and as late as November 1 at Lenwil, La., more than half of the natural transmissions by mosquitoes probably usually occur during August and September.

ACTIVE IMMUNIZATION AND PASSIVE IMMUNITY

To the Editor—In answer to the request of Dr. Daly for information concerning the advisability of instituting active immunization prior to the complete disappearance of passively conferred immunity it was stated (*THE JOURNAL* January 21 p. 211) that there seems to be no good reason why active immunization should not be started before the termination of the period of passive immunity. The value of such a procedure may be questioned as pointed out by Dr. Schagen (*THE JOURNAL* May 20 p. 1628). These diverse opinions have been of special interest to me since I have been engaged on an experimental study of this problem for the last two years. While identical in principle with the problem outlined, my work has been limited to the simultaneous production of active and passive immunity in animals previously injected with tetanus spores. Successful results in the latter case are rendered more difficult than in the case of diphtheria owing to the frequent persistence in injured tissues of tetanus spores which may germinate and produce intoxication the moment passive immunity has decayed below a protective level (a period of approximately eight to ten days). It has been found that toxoid (treated with formaldehyde) alone is of little or no value in stimulating the production of active immunity in passively immunized animals and infected animals invariably die. If however one substitutes for the toxoid a mixture of toxoid and alum (Glenny) agar or tapioca (Ramon) or injects toxoid in the form of an olive oil emulsion (Strauch C. B. Repository Injections *THE JOURNAL* April 6 1929 p. 1177) active immunity is readily produced in passively immunized animals. Following subcutaneous injection these preparations are quickly killed off as the result of the intense cellular reaction that takes place and are thereby protected against immediate neutralization by antitoxin. The injections should be repeated at least three times at intervals of from three to seven days. This procedure appears to have no noticeable effect on the efficacy of antitoxin therapy which may be carried out exactly as though no toxoid had been injected. The results in permanent active immunity by the time the passively conferred antitoxin (one or more injections) has disappeared.

PHILIP L. VARNEY M D St. Louis

ONYCHOMYOSIS

To the Editor—In *THE JOURNAL* August 15 I received a query concerning onychomycosis. *The Munchener medizinische Wochenschrift* August 4 highly recommends for this disease one or two hand baths daily followed by the application of one drop of tincture of iodine on the bed of the nail. A normal growth of the nail is reported in the case of

Book Notices

Röntgenographic Studies of the Urinary System By William L.
Lower M D F A C S Chief of Department of Urology Cleveland Clinic
and Bernard H Nichols M D F A C R Chief of Department of Roent-
genology Cleveland Clinic Cleveland Ohio Cloth Price \$16 Pp 81
with 812 Illustrations St Louis C V Mosby Company 1933

This book, compiled by a urologist and a roentgenologist has
successfully accomplished the purpose of its authors "to empha-
size the need for close correlation between the urologist and
the roentgenologist, and to show by the actual reproduction of
many films what the roentgenologist may expect to find in the
presence of various lesions and to indicate the proper inter-
pretation of the shadows which are present." The method of
presenting the facts in each case is unique. It is brief, clear
and concise and in a small space gives the reader all the
important information leading up to the diagnosis. First the
sex and age are stated. Then the roentgenographic appearance
is described although at first sight this may appear brief in
practically every case the description is complete. Under the
heading of history the chief complaints of the patient are men-
tioned. This is followed by the urinary and cystoscopic examina-
tions the operation and finally the diagnosis. On the opposite
page the roentgenograms are reproduced. These are excellent
clear cut reproductions in which a successful effort has been
made to visualize the changes present in each case. The roent-
genographic examination of each part of the urinary tract is
taken up in an orderly manner beginning with the male urethra.
A chapter is devoted to the bladder ureter and kidneys. Again
at first sight these descriptions appear to be quite brief but
after reading them one is satisfied that nothing has been omitted.
The chapter on intravenous urography covers the history of
the method the technique indications and contraindications and
concludes with a discussion of the interpretation of the urogram
made by this method. A chapter is devoted to the indications
for a roentgenographic examination of the upper right abdominal
quadrant. This is most instructive because it covers the area
where mistakes in diagnosis are only too commonly made and
the differential diagnosis is often difficult. This volume should
be of interest to both urologist and roentgenologist and should
have a place in the library of those who are interested in the
diagnosis and surgery of the urinary tract.

*Medical State Board Examinations Topical Summaries and Answers
An Organized Review of Actual Questions Given in Medical Licensing
Examinations Throughout the United States* By Harold Byrnes A B
M D Secretary New York State Board of Medical Examiners Cloth
Price \$4.00 Pp 448 Philadelphia Montreal & London J B Lippin-
cott Company 1933

This book is unique of its kind and is different from others
of a similar title. The author shows himself thoroughly familiar
with the problems of the medical student when he approaches
a licensing board for his right to practice. The advice given
to candidates in the foreword is not only sound but if read
with understanding and appreciation before taking the exami-
nation will be of more help and value to the candidate than
will the hasty perusal of the text in the hope of finding categori-
cal answers to stereotyped questions. The text is a clear
and concise presentation of the subject, which is handled in a
manner that will convey to a reader an understanding such
as will enable him to answer intelligently almost any question
pertaining to it. There are twelve chapters each dealing with
one of the subdivisions of general medicine on which questions
are usually asked by licensing boards. At the end of each

chapter is found a series of questions, answers to which can be given after reading the chapter with intelligent comprehension. Questions dealing with the same subject matter can be asked in a variety of ways. The student should not attempt to memorize parrot like answers to certain questions but should try to acquire an understanding of the subject when he will be able to give intelligent answers to questions, however they may be put.

Whitla's Pharmacy, Materia Medica and Therapeutics. Twelfth edition revised by J. A. Gunn M.A. M.D. D.Sc. Professor of Pharmacology in the University of Oxford. Assisted by H. Berry B.Sc. Ph.C. A.I.C. Head of the Department of Pharmacy, Birmingham Central Technical College and J. Clifford Hoyle M.D. M.R.C.P. Medical First Assistant and Demonstrator in Pharmacology, London Hospital. Cloth. Price \$4.25. Pp. 645 with illustrations. Baltimore: William Wood & Company, 1933.

As this textbook was first issued in 1881 the present edition celebrates more than half a century of service. It has the merit of introducing the medical student to a sufficient knowledge of pharmacy and of materia medica that he should be able to write satisfactory prescriptions. The book reflects the nomenclature as well as the preparations of the new edition of the British pharmacopoeia. Therapeutic use of the drugs is taken up in their alphabetical order which makes the book perhaps more useful for purposes of reference but less useful as a textbook because substances like digitalis and strophanthus, which should be studied together are widely separated by the alphabetical arrangement. There is also a chapter dealing with nonofficial remedies, which together with an index of poisons and their antidotes, makes the book a valuable manual to the British physician. Thoroughly in keeping with the conservative nature of our British confreres the book still clings to Latin terminology in prescribing even to the extent of rendering the directions to the patient in Latin. Another criticism that one can hardly help leveling against the general trend of the prescription writing as advocated in this and most similar publications emanating from the British Isles is that little attention if any is paid to elegance or to the palatability of the finished prescription.

Natural Childbirth. By Crantley Dick Read M.A. M.D. Cloth. Price 7s. 6d. Pp. 127 with 3 illustrations. London: William Heinemann, 1933.

Every physician who cares for women patients is aware that the element of fear much of it resulting from old women's tales, is one of the serious complications of pregnancy and labor that he must combat. Nevertheless it is a fact that the average physician does not appreciate the part played by fear in increasing the difficulties of labor. The author discusses the mechanism and management of labor from a point of view that will be of great value to every one who reads it. Within recent years methods of analgesia and anesthesia have been presented by various writers with too little regard for factors that are of the greatest importance in promoting eutocia. This work should help obstetricians to secure a more normal point of view. It is hoped that this monograph will be widely read and that the psychologic suggestions which he offers may be utilized to a greater degree in the practice of obstetrics.

Diet in Sinus Infections and Colds. By Egon A. Ullmann M.D. Instructor at the First Medical Clinic at the University of Vienna. Recipes and Menus. By Elsa Mez. Cloth. Price \$2. Pp. 166. New York: Macmillan Company, 1933.

This small book dealing with the diet in sinus infections and colds is one of the few complete works on this subject. The author does not proclaim that the proper dietary is a cure all for these conditions but emphasizes its value as a prophylactic measure as well as an adjuvant to other forms of therapy. The first part of the book deals with the development of the modern diet. The scientific data for this diet are presented and the influence of various foods is discussed. A short chapter is devoted to each of the following proteins: the alkaline diet, bread, potato, fruits, spices, spicy vegetables and fats. The importance of calcium and the restriction of salt is explained. The main characteristics of the recommended diet are the use of only fresh food, restriction of salt, a preference for alkaline food, a reduction of animal proteins and a restriction of carbohydrate. Unrefined carbohydrates are used whenever possible. The purpose of the diet is to counteract acidosis to

increase the effect of calcium in the system and to prevent an eventual lack of vitamins. The second part of the work deals with the application of this diet when and what to eat, and the preparation of the food. In discussing the management of the patient the author takes up the various possibilities for error and the importance of looking for mistakes if complications arise or the results are not as anticipated. A short chapter is devoted to testing of the urine for chlorides and its acidity. There is a fine bibliography and a supplemented appendix of recipes and menus by Elsa Mez, which should be of considerable value. Although no definite proof for the efficacy of this diet is given aside from the author's personal experience the recommendations are along the lines suggested and used by other men interested in the subject. This topic has gained in importance in the last few years and an understanding of this form of therapy should prove a valuable asset to those who are interested in colds and sinus infections.

Small Pox in Egypt: Its History and Control. By Dr. Ahmad Hilmy Bey, Assistant Under Secretary of State for Public Health, Ministry of the Interior, Egypt. Department of Public Health. Cloth. Pp. 29. Cairo: Government Press, 1933.

Here is an interesting little brochure giving a brief history of smallpox in Egypt and describing the methods used for control. At the time of the latest epidemic (1926) only about 300,000 out of the population of 500,000 in Alexandria had been vaccinated. The general vaccination of the Egyptian population put into effect as the result of that epidemic has reduced the number of cases to the lowest point ever known (ten in 1931). The attempt is being made to have all vaccinations performed by medical officers instead of, as heretofore, by sanitary barbers.

The Visual Fatigue of Motion Pictures: A World Wide Summary and Survey. Compiled and edited by Aaron E. Singer. Paper. Price \$1. Pp. 48. New York: Amusement Age Publishing Company, 1933.

Even at the present depreciated value of the dollar, the price of this booklet is about 55 cents too high. It purports to be a summary of current scientific opinion as to the question of visual fatigue in the movies but consists mostly of a series of quotations, a large share of which are either misquoted or else wrong. For example "The iris of the eye represents a lens of a camera" or "Any eye which has an anomaly will suffer [from motion pictures] from one or more of the following symptoms, headaches, neuralgia, congestion of the conjunctiva, blinking, burning, black spots before the eyes, diminution in acuteness of vision, eyestrain, double vision and blurred vision" and so on ad nauseam. Optometric opinions are quoted freely as are lay opinions on ophthalmologic topics. The recently patented "shutter-spectacle" and the much publicized "Fenbloom telescopic lens" which has been in use by the ophthalmologists for a good many years are earnestly advocated. On the whole it is rather difficult to see just what the author is driving at but whatever it is, he missed it.

Obstetrics for Nurses. By Joseph B. DeLee A.M. M.D. Professor of Obstetrics and Gynecology, University of Chicago. Tenth edition. Cloth. Price \$2.75. Pp. 666 with 269 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

This is still the most popular book on obstetrics for nurses as testified to by the fact that ten editions and numerous reprintings have appeared since it was written twenty nine years ago. Its reputation is richly deserved because it is in every sense of the word a practical book based on the author's extensive experience as a practicing obstetrician and as a teacher. There is in the book for nurses the same personal touch that characterizes the author's textbook for medical students and practitioners. The language is in terms which any nurse can understand and easily remember. The illustrations are abundant and unsurpassable for their clearness and instructiveness. The typography is excellent. The material which contains all that a nurse should know about obstetrics has been brought down to date so that the book contains information about the most recent scientific as well as practical advances including the highly useful Aschheim Zondek test. The chapter on infant feeding was contributed by Dr. Arthur Abt and is a valuable addition. At the end of the book is an outline of study which has proved to be helpful for nurses training schools. Without doubt the present edition will increase still more the popularity of this standard textbook.

The Common Causes of Chronic Indigestion Differential Diagnosis and Treatment By Thomas C Hunt BA D.M. MRCP Physician to Out Patients and Junior Medical Tutor St Mary's Hospital London Cloth Temporary price \$3.50 1 p 341 with 16 illustrations Baltimore William Wood & Company 1933

This book is a practical outline of the common causes of chronic indigestion. The term chronic indigestion is probably not the best one, but the author has defined indigestion as a name signifying a certain group of abdominal symptoms and adds that unfortunately there is no constant relationship between these symptoms and their cause. The causes described are chronic peptic ulcer, chronic gastritis carcinoma of the stomach achlorhydria, flatulence, gallbladder indigestion, chronic appendicitis, functional disorders of the colon, diverticulitis, nervous indigestion, the cardiovascular system and indigestion, alcohol indigestion, and indigestion in old age. These subjects are presented clearly and briefly. The chapters on gallbladder indigestion, functional disorders of the colon and nervous indigestion are excellent and the chapters on the cardiovascular system and indigestion, and indigestion in old age, will interest the specialist as well as the general practitioner. Diagnosis, differential diagnosis and treatment constitute the main outline of each topic discussed, but the author has managed to include the recent literature. A chapter is devoted to laboratory methods and another to history taking. This should be of value to the general practitioner and the student. The importance of laboratory tests is emphasized as related to the clinical observations. The illustrations are good. The bibliography is short but good. The book should be of value to the general practitioner and to the student who wishes more information on gastrointestinal diseases than is ordinarily furnished in standard textbooks of general medicine.

Phylogense und Geschwulstentstehung Von Dr. Max Clogner Paper Price 1.60 marks 1 p 32 Leipzig Johann Ambrosius Barth 1933

The author presents his theoretical views on the etiology of malignant tumors. He opposes the old ontogenic theory of tumor formation, according to which the cells of a malignant tumor are alleged to arise from tissue cells in a comparatively brief period, and favors the phylogenic theory, according to which the malignant cell is a descendant of those early protozoan cells that were responsible for the formation of the first multicellular protozoan organisms. While most of these protozoan cells are later transformed into metazoan cells, some of them retain their protozoan characteristics within the metazoan organism despite a phylogenic development covering perhaps millions of years. Thus the protoplasm of the malignant cell, derived from the earliest period of organic life is continually being transmitted by way of the generative substance of the sex cells. In support of his theory the author mentions the morphologically and physiologically similar behavior of protozoan cells and malignant cells, the experimental heredity of malignant disease, the universal occurrence of malignant disease in the human and animal kingdom, and the frequent changes in the stage of development of malignant disease.

Massage and Remedial Exercises in Medical and Surgical Conditions By Noel M. Tidy Sister in Charge of the Massage Department Princess Mary's Royal Air Force Hospital Hutton Cloth Price \$5.25 1 p 429 with 178 illustrations Baltimore William Wood & Company 1933

This book contains much more than the title indicates so that it was necessary to crowd the subject material. This necessitated the use of type that is entirely too small for a textbook. One is struck by the similarity to Hey Groves Synopsis of Surgery. The book contains so much surgical treatment that it might be used as a textbook for students of surgery. There is a poor distribution of space allotted to the various subjects. The physical treatment, which was the primary object in writing the book, is in many instances crowded while material extraneous to the title is given more space. For example on page 142 nearly a whole page is given to the subject of symptoms, with only a few lines referring to the physical treatment. The author was wise in the selection of material she has drawn from Mennell, Hey Groves, Jones and Lovett, and Tubby. The subjects covered include stiff joints diseases of joints synovitis arthritis tuberculosis, bursitis and diseases of bone. The subject of nervous diseases is treated extensively and makes the book unbalanced. Lesions of peripheral nerves functional nervous diseases, diseases of muscles, foot disorders deformities, diseases of the heart diseases of blood and lymph vessels,

respiratory organs, and abdominal and pelvic disturbances are discussed. In the discussion on tennis elbow, no mention is made of the importance of a bursa. The author is to be commended for her description of the position of the patient who is to be given a physical treatment. For a book on massage and remedial exercises, \$5.25 seems to be a lot of money.

Diabète et Insulinémie Par Jean La Barre chargé de cours à l'Université de Bruxelles Préface du Professeur E. Zunz Paper Price 40 francs 1 p 284 with 15 illustrations Paris Masson & Cie 1933

This presents an excellent critical study of the physiologic and pathologic variations of insulinemia. The experimental work has been done from many angles, showing variations of insulin secretion under different conditions, which forms a basis for understanding and also for therapy. Much in the book presents the author's own painstaking experimental work over a period of years, and each chapter covers a critical review of investigations carried out by other workers all over the world. Two thirds of the book represents experimental work and review of the literature, and one third represents treatment and general considerations. For any one who wants to acquaint himself with the status of the extensive experimental work on diabetes and insulin, this book is a real treasure, each page full of information. It should be read by all who treat patients with diabetes, as it will give them a more thorough understanding of the underlying physiopathology.

The Science of Human Reproduction Biological Aspects of Sex By H. V. Marshall ScD Professor of Zoology, Smith College Cloth Price \$1.50 1 p 319 with 66 illustrations New York W. W. Norton & Company Inc 1933

The social revolution has resulted in a demand for scientific information regarding the biologic aspects of sex. Other authors have dealt with the subject of sex from different points of view. This book presents only those aspects which rest securely on a sound biologic basis. The first part deals with the different physical and psychologic characteristics of men and women. Next the author considers the zoology of reproduction, the organs of reproduction and their manner of functioning. The chapter on the endocrinology of sex is excellently written and contains an outline of the latest scientific developments. The biology of human sex behavior is presented in the concluding chapter. Few books have treated the subject so comprehensively and scientifically. The literary style of the author is interesting and engaging. The bibliography offered to supplement the text has been well chosen and is a valuable addition. This book is highly recommended to the physician as well as the layman. Few modern works have presented the subject with such scientific accuracy and refreshing literary style.

Value of Blood Grouping in Anthropology By Tanemoto Furuhashi MD Professor of Forensic Medicine Kanazawa Medical College Kanazawa Japan Paper 1 p 22 with illustrations Kanazawa Japan Hogaku Kyositu Kanazawa Itadogaku 1933

This pamphlet is devoted mainly to the presentation of a series of tables giving the result of studies on blood grouping in Japan. Studies performed in Furuhashi's laboratory on 1595 families with 3636 children fully confirm the theory of triple allelomorphs. However, Furuhashi fails to give proper credit to Bernstein who first developed this theory of heredity of the blood groups in 1925. In the Japanese empire, the blood groups of a total of 324565 individuals have been determined, studies having been made in each of the forty-seven prefectures. There is no striking difference in distribution of blood groups in any prefect, and the average frequencies are group O 30.50 per cent, group A 38.22 per cent, group B, 21.99 per cent, group AB 9.38 per cent. On the other hand, rather striking differences were found among the Koreans, Formosans, Ainu and Micronesians. Studies have been made in Japan on 384 fetuses between the second and ninth months of gestation. As early as the third month the distribution of the blood groups closely approximates that of adults and the blood groups could often be determined as early as the second month. No correlation was found between blood groups, girth of chest and length of body. Finally, tables and charts show the distribution of the blood groups in the peoples of the world. The value of this method of demonstrating the relationship between races was first pointed out by the Hirsfelds in 1917.

Diseases of the Heart The Methods for Their Diagnosis Prognosis and Treatment By William D. Reid M.D. F.A.C.P. Assistant Professor of Cardiology Boston University School of Medicine Paper Price 65 cents Pp 105 Boston The Author 1933

This volume presents the author's views on certain phases of diseases of the heart in an informal way designed to be supplementary to larger textbooks on the same subject. It is strictly clinical and covers especially well the general subjects of history taking and physical examination prognosis and treatment in the manner used in bedside teaching without elaborate descriptions of diseases in true textbook style or meaningless case histories. It presupposes an organized knowledge on the part of the reader of the general field and hence is valuable, for the most part, as an aid to the medical student or practitioner, but not as a substitute for some other sources of more systematized knowledge of heart disease. It is strictly sound and conservative throughout and should be of value to any one at all interested who has not already had special training in the field.

Temas oficiales (rapports) sobre el desprendimiento de la retina I Etiología y patogenia del desprendimiento de la retina Por Dr. H. Arruga II La cura medica del distacco della retina Da G. Orio III Die operative therapie der netzhautablösung Von A. Vogt T. II I. V. Concilium Ophthalmologicum 1933 Hispania Paper Various paginations with 147 illustrations Madrid 1933

This is the official report, from the fourteenth International Congress of Ophthalmology held in Madrid last April of the symposium on detachment of the retina, and it represents the summation of present human knowledge of that condition. The report is in three parts. The first part is in Spanish by Arruga of Barcelona and deals with the etiology and pathogenesis of retinal detachment. It covers 191 pages and is profusely and beautifully illustrated with both colored and black and white illustrations, clinical and microscopic. The conclusions cover eight pages and appear in Spanish, German and English and are too extensive to permit of abstract. A bibliography of 330 references in all languages seems to cover the topic. The second part deals with the medical treatment of detachment of the retina and was written by Orio of Rome. It appears in Italian and has no illustrations. Almost all the different medical methods of treatment are discussed more or less at length.

From the statistics here compiled, an average of about 22 per cent of improvements and cures have been noted. That concluding statement of the abstract which also appears in French, German and English, will scarcely meet the approval of clinicians. Here too is added an extensive bibliography of 290 references. The third part is in German and was written by Vogt of Zurich. The illustrations are few but are excellent. The surgical treatment of detachment of the retina forms the topic of this part and the various methods are discussed at fair length. The multilingual abstract can be boiled down to the statement that the important factor in the operative treatment for detachment of the retina today is the closure of the retinal hole. The bibliography for this part contains only twenty-two references. All three parts contain the details of illustrative cases. All in all everything that is known about detachment of the retina can be found in this volume, which makes it the last word on the subject.

Surgical Anatomy By C. Latimer Callander A.B. M.D. F.A.C.S. Assistant Clinical Professor of Surgery and Topographic Anatomy University of California Medical School With a foreword by Dean Lewis M.D. Sc.D. F.A.C.S. Cloth Price \$12.50 Pp 1115 with 1260 illustrations Philadelphia & London W. B. Saunders Company 1933

While knowledge of general gross anatomy changes but slowly that of surgical anatomy has changed more rapidly as a result of the continued rapid increase in the field of operative surgery in recent years. With the advent of each new operation has come a reconsideration of the regional anatomy. Structures and relationships that were previously of little consequence assume a new importance when a new surgical approach or attack is introduced. From this standpoint Callander's Surgical Anatomy meets an important need. This is particularly true in the fields of neck and thoracic surgery in which recent advances have been rapid. The surgical anatomy of diaphragmatic hernia mediastinal tumors and chronic empyema have been considered in a new light. The technique of phrenic excision, pneumotomy, pneumectomy and operations on the pericardium and heart are given in detail. The illustrations both of the

anatomy and of the operative procedures are extensive and excellent in quality. The sympathetic nervous system has been studied in terms of the newer operative procedures on it. Much of the obsolete has been deleted, particularly with reference to the ligation of vessels and amputations. It is a work of value both to the clinician and to the teacher of anatomy.

The Elements of Medical Treatment By Robert Hutchison M.D. F.R.C.P. Physician to the London Hospital and to the Hospital for Sick Children London Second edition Cloth Temporary price \$1.50 Pp 188 with illustrations Baltimore William Wood & Company 1933

This embodies an annual course of lectures. As the author says it is not a complete treatise on medical treatment but merely a setting out of principles and their application to the commoner forms of disease encountered in practice, special attention being given to the prescription of drugs. Many of these, as well as quite a bit of the material offered, appear somewhat old-fashioned. One gets the impression of a straining at giving general currency to the idea of "team work" in drugs. The author favors four drug prescriptions patterned after the *curare cito tuto, et jucunde* pattern. Unfortunately, the pleasantness part of it is too often sacrificed to the attempt to secure the other aims of this maxim in a more or less doubtful manner. Most of Dr. Hutchison's model prescriptions are indeed far from being pleasant. On the other hand, so much clinical wisdom is contained in this book that even the experienced physician will find it full of practical inspiration.

Klinik und Therapie akuter Vergiftungen Von Dr. Ludwig Popper Assistent der I. medizinischen Abteilung des Allgemeinen Krankenhauses in Wien Mit einem Vorwort von Prof. J. Pal Paper Price 10 marks 1p 233 Leipzig and Vienna Franz Deuticke 1933

A new epoch in toxicologic literature seems to be developing, in that clinicians are entering the field and writing of their practical experience, with critical discussion of the various therapeutic measures advocated. Such a one is the present book, from the clinic of Professor Pal of Vienna, in whose section for several decades most of the cases of poisoning entering the Wiener Allgemeine Krankenhaus have been treated.

The Motion Picture as a Professional Instrument By William F. Kruse Paper Grátis Pp 28 Chicago Educational Division Bell & Howell Company [n.d.]

This monograph is an answer to frequently repeated requests for information dealing with the production of medical motion pictures on 16 mm film. It is written especially for the amateur and covers all the necessary details concerning the preparation of the "scenario" (i.e., what should be included and what omitted), the kind of lenses focusing lights, filters, supporting the camera, speed editing and titling. There is a discussion of animated motion pictures, the use of sound and cinemicroscopy. Frequent reference is made to the methods employed by different physicians in solving particular problems, and a bibliography is given of some of the more important articles dealing with medical motion pictures.

Urologie des praktischen Arztes Von Hofrat Dr. Felix Schlagintweit Urologe in München Second edition Cloth Price 8.20 marks 1p 181 with 104 illustrations Munich J. F. Lehman 1933

The author has again succeeded in furnishing a succinct though complete survey of the essentials of modern urology. A valuable feature of this monograph is the minute instruction given for the evaluation of the leading points in diagnosis and aims of therapeutic efforts, how to collect the necessary information and how to administer a purposeful therapy based on the proper recognition of the pathologic condition present.

Diseases of Old Age By F. Martin Hipscomb M.R.C.I. Major Royal Army Medical Corps Cloth Temporary price \$3.50 1p 472 Baltimore William Wood & Company 1933

This book is little more than a compilation, the source material being largely articles in standard textbooks and systems of medicine. Where the author's experience has been extensive as it apparently has in gout, the chapters are of some merit. In general however the practitioner will get little help in the recognition of the diseases discussed or in their treatment. The subjects of diabetes and hyperthyroidism for example are handled in a most unsatisfactory manner. Important details are lacking as are many modern ideas. The work will make but a limited appeal to physicians.

Medicolegal

Selection of Examining Physicians in Personal Injury Suits, Examining Physicians as Officers of Court, When Exact Nature of Injury Must be Pleading—In an action for damages on account of personal injuries the defendant applied to the court for the appointment of a medical commission to examine the plaintiff. The defendant suggested that one member of the commission be selected by the plaintiff and another by the defendant and that these two select a third member, if they should so desire. The plaintiff objected. The trial court sustained the objection and instead of appointing such a commission as was proposed appointed three disinterested physicians of its own choice. The plaintiff filed a motion to set aside the order appointing these examining physicians; the motion was overruled and the plaintiff noted an exception. Judgment was given in favor of the defendant. The plaintiff appealed to the Kansas City court of appeals. Missouri contending among other things that the appointment of the examining physicians was error.

The law said the court of appeals vests the trial court with authority in its discretion and in the furtherance of justice to appoint physicians to make a physical examination of a plaintiff. The defendant however cannot demand as a matter of right that such an examination be made. When the court makes such an appointment it does so because in its judgment the case calls for the opinions of disinterested and unbiased physicians not for the opinions of friends of either party to the suit whose testimony may be biased. The court cannot compel a plaintiff to submit to an examination by witnesses for either side but physicians appointed by the court in such cases are officers of the court. There was no showing said the court of appeals that the trial court abused its discretion in the appointment of the examining physicians. The trial court refused to admit testimony offered by the plaintiff to show that her spine had been injured on the ground that such evidence was outside the allegations of her petition. Her petition had complained that she had been greatly and permanently injured in her head, body and limbs. She contended that, since her body included her spine, her complaint of an injury to the body was sufficiently broad to include a specific injury to the spine and the nervous system. But the court of appeals could find no error in the exclusion of the proffered evidence as to the spine. The petition did not charge specifically an injury to the spine nor contain any allegation that would notify the defendant that he would be called on to defend against a charge of such an injury. The fact that the defendant might have been entitled to a more definite statement concerning the plaintiff's injuries if he had by proper motion sought to be informed concerning them was regarded by the court of appeals as without merit.

The judgment of the trial court was affirmed.—*Boggs v Gosser (Mo)*, 55 S W (2d) 722

Mandamus Not Available to Compel Readmission to State Medical School—The University of Texas maintains a school of medicine at Galveston under the control and management of the board of regents of the university. The board is authorized by statute to enact such rules as may be necessary for the successful management and government of the university and to regulate the course of instruction and prescribe by and with the advice of the faculty, the books and authorities used in the several departments. Under this authority the board by rule provided that a student who failed to make satisfactory grades in three major subjects or their equivalents or in two major subjects when the general average is less than 70 should be automatically dropped from the roll and should not be readmitted. Foley was admitted to the medical school as a student but at the end of his second year he was dropped because he had failed to attain the required standard of proficiency. He sought by a writ of mandamus to compel the board of regents to reinstate him.

A student who is admitted to the university, said the Commission of Appeals of Texas section A has the privilege of attending that institution subject to reasonable rules promul-

gated by the board of regents, in force at the time of his admission. Unless he attains the standard fixed under authority of law he is not entitled to continue in attendance, if the prescribed standard is not unreasonable nor arbitrary and is such a standard as the average student is able to meet. A rule which refuses readmission to a student who has failed to attain the prescribed standard is not unreasonable when the facilities of the school are inadequate to accommodate all who are eligible for admission. The authority to fix standards is by statute vested in the board of regents and the faculty. If a change in the rules and regulations is desired, it is a matter for consideration by the legislature. The courts will not interfere in the absence of a clear showing that the board has acted arbitrarily or has abused the authority vested in it.

The recommendation of the Commission of Appeals regarding Foley's application for a mandamus to compel his reinstatement in the medical school was adopted by the Supreme Court of Texas and the mandamus was refused.—*Foley v Buntz (Texas)*, 35 S W (2d) 80.

Health Insurance "Immediately Disabled" Construed—Under an insurance policy that provided certain benefits if the insured should through accidental means sustain bodily injuries which independently and exclusively of all disease and all other causes immediately, continuously and wholly disabled him from the date of the accident the plaintiff, the beneficiary under the policy, sued the defendant insurance company. On April 3, 1928, the insured had run a sliver of wood into one of his fingers. He worked at his usual occupation up to and including April 9. On the following day he was treated by a physician and on April 11 he was taken to a hospital suffering from blood poisoning. He died April 18. The insurance company contended that the accidental injury did not immediately, continuously and wholly disable the insured from the time of the accident and that consequently the insurer was not liable under the policy. The word "immediately," said the Supreme Court of Kansas, is not synonymous with "instantly," "at once" and "without delay." A disability is "immediate" within the meaning of such an insurance contract as the one under consideration if it follows directly from an accidental hurt within such time as the processes of nature consume in bringing the person affected to a state of total incapacity to prosecute every kind of business pertaining to his occupation. The Supreme Court therefore affirmed the judgment of the trial court in favor of the plaintiff.—*Thomas v Mutual Ben Health & Accident Assn (Kan)*, 18 P (2d) 151.

Lungs After Treatment of Asphyxia Neonatorum — Murphy and Bauer compare the pathologic changes in the lungs of thirty asphyxiated infants, who were given artificial respiration in the Drinker respirator but who died within twenty-four hours after birth, with thirty who had not received this means of artificial respiration. Of these thirty deaths, 70 per cent were the result of either intracranial injury or prematurity. There was no death due to a pulmonary condition. A slight increase in the incidence of pulmonary congestion followed the use of the Drinker respirator and indicated that the treatment had an appreciable effect on the contents of the chest. Artificial respiration had no influence on the kind of cellular elements observed in the air passages but may have drawn amniotic debris from the bronchioles to the alveoli. Otherwise no gross or microscopic changes were recognized in the lungs of the treated infants that had not been seen in the lungs of untreated infants. In no case was any injury done to the respiratory tract by the use of the respirator. When asphyxia is due to atelectasis it is probable that the previously used 10 cm of negative pressure can be raised safely to 15 cm. Furthermore it may be advisable to alternate this higher degree of negative pressure with an equal amount of positive pressure instead of with atmospheric pressure as has been used as a routine measure in the past.

Chemical Allergy and Nirvanol Sickness—Schuck and his associates treated twenty-five patients suffering from chorea with the original nirvanol (phenylethylhydantoin), which contains equal parts of the levoform and the dextroform. The daily dose was 0.3 Gm. It was given for from eight to ten days and was discontinued with the appearance of nirvanol sickness. Twenty-one patients showed symptoms of nirvanol sickness and four did not. Of twenty-eight patients, some of them having chorea and others epilepsy, twelve were treated with the levoform and sixteen with the dextroform of phenylethylhydantoin. The daily dose of levophenylethylhydantoin was 0.15 Gm. This dose does not correspond in its power to produce sickness to 0.3 Gm. of the original nirvanol. Of the twelve patients treated with levophenylethylhydantoin, sickness resulted in seven; no symptoms having occurred in five. Sickness developed in five patients treated with dextrophenylethylhydantoin, eleven remaining free from symptoms. The authors believe that a beneficial effect is achieved with nirvanol. Children treated with dextrophenylethylhydantoin showed an

improvement in the chorea even without the development of a rash, which indicates that the rash and other symptoms of nirvanol sickness may not be essential for an effective treatment

Diagnosis of Early Tuberculosis — Sullivan and Jones demonstrate that the monocyte plays an important part in tuberculosis. An increase in the number of monocytes of the circulating blood is indicative of activity. A study by the Sabin technic of the number of monocytes and the relative proportion of monocytes to that of lymphocytes that is the monocyte-lymphocyte ratio often proves of invaluable assistance in diagnosis. In active tuberculosis the monocytes are markedly increased and there is a reversal of the monocyte-lymphocyte index. In arrested tuberculosis there is an increase in the lymphocytes with the total number of monocytes increased but less in number than the total lymphocytes. There is a storehouse for monocytes in the tuberculous patient, which does not exist in the normal nontuberculous subject. If the total number of monocytes and the monocyte lymphocyte ratio is determined before and after the administration of tuberculin subcutaneously, the blood of patients in which a definite focal reaction is obtained will show a marked increase in monocytes and a shift in the monocyte-lymphocyte ratio. This simultaneous provocation of focal reaction and increase in circulating monocytes is strong evidence of the presence of tuberculosis.

Ketogenic Diet in Normal Persons—Apperly and Norris studied the blood changes produced by the ketogenic diet in three normal subjects. They observed that alkalemia was almost constantly present accompanied by a fall in the carbon dioxide of the plasma and the red cells. They suggest that the alkalemia is the result of hyperpnea produced by direct stimulation of the respiratory center by certain ketone derivatives in the blood that in their experiments this effect outweighed any acidemia produced by ketonic acids and that the failure of the ketogenic treatment of many cases of epilepsy and asthma is due to the relative preponderance of the former effect. They believe that a study of any of the conditions tending to raise the ketonic acid acetone ratio would be of benefit in the treatment of epilepsy and asthma.

Posttraumatic Cystic Disease of Carpal Bones—From a study of five cases of posttraumatic cystic disease of the carpal bones and the literature, Malone concludes that the conditions as described by Preiser and Kienbock are not separate clinical entities. A standard diagnostic name should be adopted, the most inclusive one up to the present time being 'posttraumatic cystic disease of the carpal bones'. The disease is much more common than the literature indicates. The arthritic element as a factor in the production of pain must not be overlooked in these cases. The term osteitis should not be used in connection with this condition, at least not without qualification. The treatment is not satisfactory and depends on the stage of progress when discovered. Conservative treatment in the early stages, in the form of rest, heat and massage, leads to a good result or at least a useful wrist in about half of the cases. The experience of nearly all writers has been that, when the fracture is followed by pseudarthrosis and cystic degeneration or fracture follows the cystic change, union rarely, if ever, takes place. In these cases the only treatment is either partial or total extirpation. The results from operation do not give an absolute restoration of function. Müller reports complete recovery in a case in which he did an evacuation of calcium and bony debris with preservation of the actual bone shell.

Tuberculosis of Diaphysis—Bromer and Downs report the history of a white man, aged 76 who was suffering from a destructive tuberculous lesion in the shaft of the fibula. The roentgenographic appearance of the lesion showed no characteristics comparable to any of the various types of lesions previously described. In the literature, only one type of lesion that resembles the appearance of the authors' case is reported. Caan, in describing tuberculous lesions solely affecting the diaphysis, describes the central and peripheral types. The case of the authors seems to resemble Caan's second type. The lesion was definitely superficial. A tumefaction was present. An additional focus soon developed in the humerus. No other tuberculous foci were found on the first examination. In many respects, this case is similar to the description of Caan's second type.

Actinomycosis of Spine—The descriptions of previous writers and the observations in their case lead Tabb and Tucker to believe that the roentgen observations in actinomycosis of the spine are as follows: 1 This disease usually attacks two or more vertebrae. It produces rarefied areas which are sharply defined, and apparently normal bone texture may be adjacent to and between these rarefied areas. 2 It involves the bodies, pedicles, laminae and the different processes of the vertebrae, also the adjacent ribs apparently without any predilection for the bodies, which contrasts strongly with tuberculosis, in which the vertebral body bears the brunt of the attack. 3 The intervertebral spaces show little if any narrowing, and a marked destruction of the vertebral body or bodies may take place without any collapse or kyphosis. The opposite is usually the case in tuberculosis. 4 Large perivertebral abscesses form rather early and are a constant finding. The organism can be found when a sinus has formed. 5 Sequestration has not been encountered. 6 There is usually lung infection when the spine is involved. Roentgen examination of the lungs will show the involvement and the organism may be detected in the sputum. Potassium iodide has been reported to be specific in lung and appendiceal cases. Surgery is valuable when the part involved is of an operable nature. Wide excision and curettage have been reported successful. Local injections of phenol in strong solutions, or even application of crystals, is advocated by some. Roentgen rays and radium have been used in conjunction with potassium iodide therapy, but with little noticeable effect, as all the cases so extensively involved terminated fatally. Vaccines have been advocated but none are available. Mechanical support is indicated. The authors are giving their patient 125 drops of saturated solution of potassium iodide three times a day by mouth. He also receives an intravenous injection of potassium iodide once daily. A modified Taylor back brace is being worn and he is receiving a series of high voltage roentgen treatments to the spine. There seems to be some improvement.

Choriomas of the Uterus—Black states that a uterine hemorrhage or a blood tinged discharge following pregnancy (especially a hydatidiform mole) with a positive Aschheim Zondek test should arouse suspicion of a chorioma. While 457 per cent of choriomas follow moles only about 1 per cent of moles are followed by chorioma therefore a hysterectomy or large doses of radium are not justifiable in young women with moles. The diagnosis of typical cases of choriocarcinoma from the histologic observations and clinical symptoms should

not be difficult. When a diagnosis is made, a panhysterectomy should be performed, followed by irradiation. As embryonic cells are sensitive to radium rays, radium is a good prophylactic and curative agent in chorioma in selected cases. Repeated Aschheim-Zondek tests following moles and especially following hysterectomy for chorioma are of paramount prognostic importance. Patients with mole pregnancies should be watched for several months. However if an Aschheim-Zondek test is negative, one may feel reasonably assured of no further trouble.

Pneumothorax with Aortic Aneurysm and Pulmonary Fibrosis—Ketterer reports a case of spontaneous pneumothorax with aortic aneurysm and pulmonary fibrosis in which the roentgen observations of pulmonary tuberculosis were ruled out clinically and by laboratory tests. The history, together with the roentgen observations of the aneurysm, indicated syphilis. The therapeutic test failed to have any appreciable effect on the pulmonary fibrosis after five months of anti-syphilitic treatment. The fibrosis may have been of syphilitic origin. The history of prolonged exposure to coal dust, together with the fact that pneumothorax is a rather frequent accident in these cases and with the other etiologic factors eliminated led the author to believe that the aneurysm was incidental and that the pneumothorax was caused by the pneumoconiosis.

Pulmonary Embolism from Arsenicals—Shivers reports a case in which death resulted from an injection of neoarsphenamine and gives a summary of forty-seven cases of accidents from arsenical drugs and a case of death from salyrgan reported in the literature. A large part of the deaths are due to pulmonary embolism resulting from a combination of the drugs with the plasma proteins. An acid reaction of the drug as indicated by a pH value below 7, appears to be the cause of the precipitation of the drug in the blood. If the pH of the drugs is below 7, neoarsphenamine, ar-sphenamine, and sulpharsphenamine will precipitate in dog's serum in vitro. If the pH of the drugs is below 7, neoarsphenamine, ar-sphenamine, and sulpharsphenamine will precipitate in rabbit's serum in vivo causing pulmonary embolism. The author outlines a method whereby the combination of bromthymol blue with the drugs in ampules will enable the physician to determine at the time of injection whether the drug is suitable for administration.

Bromthymol blue has a pH range from 6 to 7.8 and is yellow on the acid side and blue on the alkaline side. It was found to have a sharp end-point at pH 7 when combined with neoarsphenamine in which case it gives a green solution if alkaline and a yellow solution if acid. The amount of dye which must be combined with the drug to give a satisfactory color is 0.8 mg. per ampule of drug. When an accident does occur the patient should be treated for shock, with lowered head, heat and morphine, if the pain is severe. Epinephrine hydrochloride in a dose of 5 minims (0.3 cc.) of a 1:1,000 dilution should be administered intravenously followed by an intramuscular injection of 1 cc. of the same dilution. Sodium thiosulphate in 15 grain (1 Gm.) intravenous doses has a marked action in decreasing the toxicity of drug emboli and in hastening their absorption. The patient should receive one dose of thiosulphate intravenously at once, and this should be repeated daily until no signs of reaction remain. If embolic pneumonia occurs, symptomatic treatment, counterirritation and the administration of sodium thiosulphate and of oxygen seem to be the only methods that are of value. Statistics indicate that in 20 per cent of the cases of accidents the patients may recover.

Influence of Borderline Rays on Pathogenic Fungi—Muskatblit and Ouspensky made twenty-two experiments with five different species of fungi taken from seventeen patients. Doses up to 50,000 roentgens did not influence these fungi: *Microsporon lanosum*, *Microsporon audouinii*, *Trichophyton crateriforme* and *Achorion Schonleini*. The results with *Trichophyton violaceum* were different. The doses up to 30,000 roentgens had no effect. However, 50,000 roentgens in two experiments completely inhibited the growth, the exposed hairs remained sterile, while the control material gave numerous cultures. In the third experiment with the same species only temporary inhibition was observed. Cultures from the exposed material started to grow later, they were at first smaller than the controls and only three months after planting reached the same size and development as the latter. Fungous cultures which grew from the hairs irradiated by borderline rays did not show any peculiarities in their gross or microscopic morphology.

Nonspecific Dermatoses—From a study of two patients with dermatitis herpetiformis and four with eczema who were subjected to eighteen observations made over a period of from one to three months, before and during spleen extract therapy, Cornbleet concludes that in dermatitis herpetiformis clinical improvement was associated with (1) increased capillary permeability, (2) an increase in the carbon dioxide content and pH of the blood, (3) a decrease in the potassium/calcium ratio, (4) an increase in inorganic serum phosphorus, and (5) a decrease in blood cholesterol. In chronic eczema the only correlation noticed was a shortening of the blister time, which indicates increased arteriolar sympathetic tone. Injections of spleen extract cause a decrease in the eosinophil count which lasts for about three days. This change in the number of eosinophils cannot be correlated with clinical changes. Previous injections of spleen extract decrease the inflammatory response of a positive patch test. There are no histologic changes in a dermatitis from the use of spleen extract. At times spleen extracts are of distinct but limited value in eczema and other nonspecific dermatoses.

Extract of Spleen in Dermatoses—The clinical experience of Wien and Perlstein with a purified aqueous extract of hog spleen indicate that it is of distinct value in urticaria, dermatitis herpetiformis and secondary toxic exfoliative dermatitis. Spleen extract has limited usefulness in the temporary alleviation of certain phases of the subjective sensations in eczema. It tends to decrease the pruritus and to shorten the period of acute. It is of value as an adjunct to local therapy in resistant cases of dermatitis or as stated by Gate and Charpy it is an addition to be used in stubborn disorders especially for the relief of itching. However treatment must be prolonged with a series of injections approximating 10 Gm. of spleen substance being given at each injection over a period of time varying with the individual case. The more concentrated solution has the advantage of less fluid volume in each injection but the disadvantage of more local pain and reaction. The spleen extract is relatively nontoxic. However the authors were unable to substantiate Paul's finding of instantaneous cure by the use of spleen extract.

Cataract and Diabetes—Kirby examined eighty-eight diabetic patients under treatment to correlate the ocular observations with the general condition. Opacities of the lens were found in 64 per cent of this group. Of these 70 per cent had the opacities in the senile cortex. The severity of the diabetes did not influence the incidence of the opacities. The duration of the disease had a bearing, as the greatest proportion of cases in which opacities were present was found in the patients in whom the disease had existed for more than five years. Opacities of the lens were found in 70 per cent of the diabetic patients who showed in addition a recognized condition of general vascular hypertension. It was found that arteriosclerosis both general and local in the eye is an important complication or coincidence in diabetes, and that many of the ocular lesions could be ascribed to the vascular disease rather than to the diabetes. Retinal lesions in the form of hemorrhages exudates or edema or changes secondary to these were found in 40 per cent of the diabetic patients under treatment whose lenses were clear, while such lesions were found in 53 per cent of those with incipient cataract. A greater proportion of diabetic patients with incipient cataract than of those with clear lenses have retinal lesions, although such lesions do not necessarily accompany the formation of cataract. However, the greater number of diabetic patients with advanced cataract have suffered from retinal lesions.

- *Electric Thermoscope as an Aid in Diagnosis of Acute Mastoiditis Preliminary Report J Daley New York—p 679
- Effect of Destruction of One Labyrinth on Reactions to Rotation E L Ross and A Olsen Chicago—p 684

Abscess of Brain Following Otitis Media—Faunce and Shambaugh are inclined to believe that the incidence of abscess of the brain following mild transitory otitis media is greater than is generally appreciated. The history of otitis media is disregarded or not obtained and the patient dies before a diagnosis is made or necropsy reveals an abscess of the brain in the presence of normal temporal bones. The final diagnosis being abscess of the brain of unknown origin. The fact that the authors observed three such cases in the course of three months half the total number of abscesses seen in this period would indicate that the condition is probably not rare. Any case in which vague or definite signs of intracranial disease develop and in which a history of antecedent otitis media can be obtained should be considered a possible case of abscess of the brain.

Electric Thermoscope in Diagnosis of Mastoiditis—Daley observed that, in acute infections of the middle ear when mastoiditis is suspected, the thermoscopic reading as compared with that of the normal tympanum varied from plus 0.5 to plus 2 C. In using a normal drum as a means of comparison, the hot point is placed in the normal ear and the testing point is placed in the involved ear. In the event that both ears are involved, the author uses the mouth as his standard of comparison, the hot point is then placed in the mouth and the testing point is inserted in the ear that is to be tested. Under these circumstances the reading varies from 0 to plus 1.5 C. If repeated tests show a continued or persistent plus reading the infection is not resolving and the mastoid bone is undergoing pathologic changes. On the other hand, if such readings of the instrument indicate that the differential temperature is dropping and becoming equalized, one may be sure that the infection of the ear is resolving.

Removal of Lining Mucous Membrane from Frontal Sinus—The experiments of Hilding brought out that when the normal frontal sinus of the dog is denuded of mucous membrane and the scalp is sutured over it without drainage, the sinus usually fills with scar tissue that obliterates the cavity. In exceptional cases there is partial restitution of the sinus with regeneration of the lining epithelium. Under some circumstances a smaller cavity forms, the walls of which are composed of thick white connective tissue, devoid of epithelial covering and over which epithelium apparently cannot grow. This connective tissue shows no sign of inflammation even if exposed to air. Under other conditions, epithelium will grow over this heavy scar tissue. In some instances it appears to lie directly on the scar tissue and in other instances it lies on vascular submucosal tissue. If portions of epithelium are left within the sinus cysts filled with mucin form within the obliterating scar.

Diathermy in Angina Pectoris—Hyman applied diathermic currents to the heart in a series of eighty-seven patients presenting symptoms of chronic coronary thrombosis whose electrocardiograms showed electrodynamic deviations of the terminal ventricular complex usually associated with this condition. In the majority of instances, symptomatic relief was obtained even when standard methods of drug therapy had failed to produce any lasting benefit. Simultaneously with the clinical improvement in the patient there has been a change in the electrocardiograms: the previous negativity of the T waves is first lessened and then a normal positive deflection is obtained. The apparent explanation of the return to a normal electrodynamic status of the heart lies in the fact that exposure to diathermic current increases blood flow to an impoverished myocardium and that with a disappearance of the partial

anoxemia, the myocardium tends to return to its former normal physiologic mechanism. The records indicate that no patient has been treated earlier than six months or longer following the last seizure. The author is of the opinion that diathermic therapy will do more harm than good in the acute and subacute stages of coronary disease and that there is more or less hazard to be anticipated in actively exposing such hearts to the diathermic current. He knows of one fatal instance in which diathermy was used on the sixth day of a coronary attack. In the subacute stage of myocardial infarction when a negative T wave has already developed in one or both of the significant leads, exposure of the heart to diathermy may increase the amplitude and negative activity of the T wave. The author saw four such instances in patients who were subjected to too early diathermic treatment.

Localizations of Poliomyelitis Virus—The experiments of Faber and Gebhardt indicate that about four days after intranasal instillation the virus of poliomyelitis establishes its initial focus within the central nervous system in the olfactory bulbs. From this initial focus the virus spreads (on the fifth and sixth days) through the olfactory tracts and their connections in the brain stem. A secondary focus in the hypothalamus is first established. From this two main channels can be discerned: first to the medulla, second to the thalamus and midbrain. On the seventh day the virus can first be detected in the spinal cord. It is widespread but is found in larger amounts in the cervical than in the lumbar segment. It is present in both the anterior and posterior horns (either in equal amounts or in slightly larger amounts in the posterior). It is also present

in the intervertebral ganglions. The authors surmise that the main route of infection of the cord is not from the medulla but along the sensory tracts presumably from the thalamus. Certain portions of the central nervous system were never found to contain demonstrable quantities of virus: these were the cortex of the frontal and parietal lobes and the cerebellum. The olfactory cortex was only once found to contain virus, this occurred on the seventh day and in small amounts and presumably had its source in the olfactory bulbs. The experiments of the seventh day suggest that the virus had died out in areas previously infected (in the hypothalamus and thalamus particularly) while continuing, apparently undiminished, in the midbrain and medulla and spreading to the cord. These observations are in harmony with the general contentions of Fairbrother and Hurst that virus is better adapted to survival in the lower portions of the cerebrospinal axis than in the higher. The authors conclude that both the experimental disease and the disease as it occurs in man appear to present the features of an infection spread through nervous tissue only. It is unnecessary to assume that at any stage of its progress during the incubation period or later, systemic or general extraneuronal infection is present.

Relation of Poliomyelitis to Louping Ill—The results of the work of Schwenker and his associates show that louping ill and poliomyelitis immunologically are not closely related. Although relatively few experiments were performed, the data obtained were sufficiently decisive. Certainly nothing was found to indicate that one might be able to immunize human beings against poliomyelitis by the use of louping ill virus. In addition to the negative observations, a certain amount of useful information was also secured, namely, (1) monkeys can be solidly immunized against louping ill by intraperitoneal injections of virus and partially protected by intramuscular administration of the active agent, (2) during the process of immunization no signs of involvement of the central nervous system are manifested, and (3) serums from monkeys immunized by intraperitoneal injection contain antibodies capable of neutralizing the virus.

Standardization of Antiserum—Kolchin presents facts corroborating the observations of Frazer and Plummer on the use of rabbits for titration of antitoxic serums of hemolytic streptococci. This titration is done on the basis of the principle applied to titration of antiscarlatinal serums on children. Full grown white rabbits with thick skin and preferably heavier than from 2400 to 2500 Gm were used for titrations of serums with at least the same success as the chinchilla rabbits. The variation in the degree of rabbit skin susceptibility as expressed in the number of skin test doses evoking a reaction not less than 10 by 10 mm is similar to the same variation on human and goat skin. The incidence of rabbits giving a positive reaction to from 1 to 5 skin toxin doses (human) of a sterile toxin is about 40 to 60 per cent. A skin reaction produced by an intradermal injection on the ventral side of the ear as described by Velde was utilized by the author as a preliminary test for selection of susceptible rabbits. The test dose most suitable in neutralization tests for serum titrations was

found by the authors to be the same as in tests on man. Test doses greater than 5 skin toxin doses can also be used in groups of rabbits in which reactions to 1 and 5 skin toxin doses in a preliminary ear test were found to be below the adopted standard. Serum values obtained in titrations against different doses of the same toxin are about the same.

Phenyl-Mercuric Compounds—The experiments of Weed and Ecker show that, despite the high bactericidal action of phenyl-mercuric salts they are relatively nontoxic to animals, whether given orally, intraperitoneally or subcutaneously. Isotonic phenyl-mercuric chloride used to irrigate the bladders of rabbits gave comparatively less inflammatory reaction than did saline solution. A lethal dose of phenyl-mercuric nitrate given intravenously produced acute nephrosis. The digestive action of trypsin and pepsin was not inhibited by the presence of phenyl-mercuric chloride. Vaccines prepared by treating cultures of *Bacillus typhosus* and *B. proteus* with phenyl-mercuric nitrate retained their antigenic power as regards the production of agglutinin. Human serum treated with phenyl-mercuric chloride retained its precipitinogenic power. Diphtheria toxin treated with phenyl-mercuric nitrate for five months retained its original minimal skin reaction dose. The lytic action of lysozyme was not inhibited by phenyl-mercuric chloride. The presence of phenyl-mercuric chloride did not interfere with the action of complement.

Journal of Nervous and Mental Disease, New York

- *Isolated Neuritis of One Sensory Filament of Mixed Nerve A Gordon Philadelphia—p 617

Value of Hoffmann Sign—Fay and Gotten point out that the so-called Hoffmann sign appears to be a delicate reflex phenomenon associated with organic diseases of the nervous system situated above the cervicoventral region. It compares favorably with the Babinski reflex as a reliable index of organic disease in the cortical spinal pathways. It may at times appear without a Babinski reflex when the lesion is focal to the fibers or areas concerned in motor function of the upper extremities. Tromner described the sign in the following way: "Snap the tip of the nail of the middle finger or index finger of the patient with your own middle finger. If a definite flexion of all fingers and thumb results, there is organic disease above the flexor centers. This phenomenon is found always and only in spastic paralysis of the arm." The results of the authors' study of 393 normal students, 285 patients without organic disease and 339 patients showing organic nervous disease have convinced them that the Hoffmann reflex is valuable and reliable and should find wider application in routine clinical examinations. Twenty-one of the students gave a positive Hoffmann sign as compared to fourteen giving a positive Babinski reflex. Two patients in the group without organic disease gave a positive Hoffmann sign and only one gave a positive Babinski reflex. Of the patients showing organic nervous disease 132 gave a positive Hoffmann sign and 140 gave a positive Babinski reflex.

Isolated Neuritis—Gordon describes an isolated neuritis of one sensory filament to the exclusion of others of a mixed nerve. The few cases of such a neuritis reported in the literature have reference to the extremities and more frequently to the upper than to the lower ones. The special interest of the present case lies in its occurrence in a part of the body other than the limbs. The auriculotemporal nerve was affected after a blow to the left side of the face. The clinical picture corresponds with mathematical exactness to the anatomic distribution of that small nerve branch.

Tomato and Orange Juices, and Urinary Acidity—Saywell and Lane report experiments with men on a basal diet and on the same basal diet supplemented by tomato and orange juices. They observed the following results when the juices were added to the basal ration: 1 An average increase of the urinary pH of 12 pH units was produced by 1,000 cc. of tomato juice taken daily. An equal quantity of orange juice produced a similar average increase of 105 pH units. 2 Corresponding decreases in the ammonia excreted and in the total acidity were noted. The average changes produced by the two juices were approximately the same. 3 There was an increase of the alkali reserve calculated according to the method of Fitz and Van Slyke, above the normal for each subject. This increase was quite marked for both juices. 4 There appeared to be a correlation between the alkalinity of the ash and the reaction of the urine. A more basic reaction was associated with the higher ratio of soluble alkalinity to insoluble alkalinity of the ash. The tomato juice exhibited the higher ratio and produced a somewhat larger change in reaction. 5 An increase occurred in the organic acids excreted when tomato or orange juice was added to the basal ration. 6 The average oxidation of the organic acids of tomato juice was 90.7 per cent, while that of orange juice was 93.8 per cent.

Treatment of Arthritis—Berris describes a method for the production and control of hyperthermia. The meal preceding the treatment is replaced by a liberal allowance of fluids. During treatment, tepid water is allowed. Otherwise the usual dietary regimen is followed. The patient is placed in a large wooden, air-insulated cabinet so arranged that the patient reclines on a rubber couch with his head in the open air, with the thermostat in position, the cabinet is closed and the electrical heating element and water vaporizer are put in operation. Pulse readings are made every five minutes. Blood pressure records may be made by leaving one arm of the patient outside the cabinet. Body temperatures of from 102 to 103 F are usually attained in from forty to sixty minutes, and from 103 to 105 F in from sixty to ninety minutes. These levels are attained with a cabinet temperature which usually does not exceed 130 degrees. Restlessness and apprehension are allayed by applying cool cloths to the patient's head and by massaging the head and neck. When the predetermined level of hyperthermia has been reached, the main switch of the apparatus is opened and the patient is quickly dried and transferred to the ward. Heat loss is minimized by wrapping the patient in heavy woolen blankets. The temperature level may be well sustained for from four to eight hours by the use of hot water bottles. When the mouth temperature has dropped to 99 F, body massage and manipulation of affected joints and muscles are instituted and the patient is given a shower or an alcohol rub and is discharged. The entire period of treatment usually consumes from four to six hours. Three treatments weekly for three weeks constitute a course, temperature levels of about 102 F being used. As many as twenty treatments over a period of five weeks have recently been given. No other therapy is administered during the period of these treatments. Of the author's series of twenty cases of various types of arthritis, resistant to other methods of treatment 75 per cent have shown definite improvement. The improvement obtained seems to depend on peripheral vascular dilatation and improvement in local circulation.

Chronic Endocervicitis—In treating chronic endocervicitis with the cautery Maloney uses no anesthetic. He places the patient in the dorsal recumbent position, exposes the cervix by a Graves speculum and washes the vagina with a quart of compound solution of cresol. The speculum is rotated so that the solution comes in contact with all parts of the vagina. After sponging the cervix and vaginal walls he freely applies mercurochrome. The usual technic is to make a linear cauterization in normal tissue outside the margin of the inflamed area and then thoroughly cauterize the entire outlined area, going well up into the canal but not to the internal os. The depth necessary to insert the cautery tip varies from a fourth to a half inch depending on whether there are cysts or not, but the entire infected gland-bearing area is thoroughly cauterized regardless of how deeply it is necessary to go and the entire procedure is done at one sitting. He then reapplies mercurochrome and inserts a cotton tampon dipped in a solution of sulphurated bitumen and glycerin. The patient is instructed to

remove the tampon in two days and to return in three days and, thereafter, two times a week until complete healing has taken place. This averages about six weeks. At each visit the vagina is gently syringed out with compound solution of cresol, mercurochrome is applied to the whole vagina and the patient is warned not to take douches. After the slough has disappeared, the granular area becomes smaller and smaller until it is entirely covered by normal epithelium, the canal being the last to heal. If the granulations become exuberant or seem to require stimulation, they are touched up with a 10 per cent solution of silver nitrate instead of being treated with mercurochrome. There are a few contraindications for the use of the cautery in treatment of the cervix. Acute vaginal or cervical inflammation should be treated with hot douches and allowed to subside before the cautery is used. Infections, such as acute endometritis, salpingitis and pelvic cellulitis, should be allowed to subside before cauterization is done. Pregnancy in the first three months is not a contraindication in properly selected cases, but in acute inflammation or a history of a previous abortion it should not be performed.

Use of Typhoid Vaccine in Gonorrheal Infections—McMillan treated eleven patients infected with gonococci by injecting triple typhoid vaccine intravenously, thereby inducing a marked hyperpyrexia. In every patient a drop in temperature occurred at a period varying from two to four hours after the injection of the vaccine and varying in amount from one to four degrees. This drop was followed by a secondary rise of from one to four degrees. The profile curve is always dicrotic. With an initial dosage of 0.3 cc the lowest fastigium is 101.5 F, the highest 104.5 F. The use of this method produces great prostration and usually emesis. The effects of the second injection of 0.5 cc, two or more days later is but a repetition of the clinical picture of the 0.3 cc injection except that the second injection appears more effective than the first to influence favorably the course of the infection. In no case in the series was albuminuria reported. In all cases the improvement noted was permanent.

Methylene Blue and Methemoglobinemia—Steele and Spink present two case of poisoning which showed the presence of methemoglobin in the blood. Both patients were given an intravenous injection of a 1 per cent saline solution of methylene blue with resultant recovery. Both patients ingested poisons which caused grayish blue cyanosis, stupor and chocolate colored

blood with positive spectroscopic test for methemoglobin. The vomitus of one patient was not analyzed, in the other, the analysis revealed acetanilid in large amount. Fifteen minutes after the administration of the dye there was a disappearance of cyanosis, a return to consciousness, and the methemoglobin brand was absent in the patient who ingested acetanilid while the blood of the other patient was normal in color. The authors conclude that the two possible explanations of the action of methylene blue are that (1) the dye may combine directly with the poison to form a nontoxic compound which is excreted or (2) the poison may combine with hemoglobin to form methemoglobin, but the dye acting as a catalytic agent, may accelerate the reversal of this process.

Pregnancy with Cirrhosis of Liver—Fenney and King relate the history of a case of proved cirrhosis of the liver complicated by pregnancy in which the first laboratory studies made three months before delivery in an effort to determine the extent of liver damage, were all essentially normal except for the sugar tolerance curve. This showed an absence of the usual transient hyperglycemia seen in persons with normal liver function. The fatty acids of the blood were definitely increased above normal, though whether the damaged liver was responsible is open to question since the pregnancy alone could account for such an increase. The second series of analyses was made one hour before delivery. The high level of the fatty acids of the fasting blood suggests that at that time the liver was beginning to show the effect of the superimposed pregnancy. Two weeks after delivery this level had fallen to that of three months before delivery. Both the epinephrine fatty acid and sugar curves were distinctly abnormal and pointed to considerable liver insufficiency despite the removal of the burden of pregnancy. Six months later the curves were nearer normal though still suggesting definite liver damage. At no time was there any evidence of toxemia.

Tuberculous Endophlebitis with Obliteration of Superior Vena Cava—Schmeisser and his associates report the second case of tuberculous endophlebitis with obliteration of the superior vena cava. The occlusion was complete. The blood from the entire systemic venous circulation except that from the heart entered the right auricle by means of the inferior vena cava. The entire systemic venous circulation except that of the heart was in a state of chronic passive congestion. The

collateral circulation is recorded diagrammatically. The authors believe that the anomaly of the left common carotid artery taking origin from the innominate artery suggests that the closure of the auricular orifice of the superior vena cava may have been congenital. After a congenital closure, tubercle bacilli from the focus in the lung or in the pleural cavity could have entered the circulation and could have settled out from the blood into the superior vena cava, causing the endophlebitis.

Treatment of Pregnancy Syphilis in Trimesters—In their 1000 cases of syphilitic pregnancies, Remberger and Toombs reduced syphilitic tragedies, including new born infants stillbirths and abortions, from 100 to 35 per cent. Pregnancy does not alter the reaction. Positive Wassermann and Kahn tests indicate syphilis, though there is no clinical evidence. The earlier treatment is instituted, the more likely is one to obtain living normal babies. The serologic evidence at birth is more important than clinical evidence. Regardless of treatment there is yet a small percentage of syphilitic tragedies. Even though the patient has had intensive treatment and is serologically negative she should have treatment in each succeeding pregnancy. Treatment has no deleterious effect on the mother or the baby, regardless of the trimester in which it is instituted. Approximately 80 per cent of the patients seen in early infancy and kept under observation and treatment for two years have remained free from positive serologic tests. Infants born of syphilitic mothers who have negative blood and spinal Wassermann reactions are kept under observation and checked every three months for two years.

*Need for Standard Method of Estimating Blood Pressure G A Stephens—p 121

Estimating Blood Pressure—Stephens in estimating the blood pressure, places the armlets (2 by 11 inches) of two sphygmomanometers on one arm, the one below the other he inflates the upper armlet until the pulse ceases to be felt, when the reading on the upper dial gives the systolic pressure, and then inflates the second armlet until the needle on the upper dial is moved upward a point, when the reading on the lower dial gives the basic pressure. He believes that his method is mechanical and objective, requiring the minimum of skill and judgment, whereas the auscultatory method depends on the capacity of the physician to detect and discriminate between various sounds which are not readily heard. The limitations of the auscultatory method are in cases of irregular hearts, when there is a difference of intensity between successive sounds, when the arm is too thickly covered with fat when there is no artery large enough to auscultate and when one has no ear for differences of sound and is unable to detect the right sound at the right time.

Arthritis of Hip Joint—In his investigation of arthritis of the hip in ninety-seven children Butler found that fifty-six were tuberculous. Thirty-four were suffering from a transitory arthritis only without any abnormality being shown by roentgenograms at any time. Seven had a transitory arthritis as a reaction to a localized bone infection near the joint, without true joint infection. A transitory arthritis without roentgen changes is common in childhood and is frequently diagnosed as tuberculous. Sometimes it may be traumatic in origin, but more often it is infective, the infection being often secondary to a focus elsewhere in the body. The prognosis of this transitory arthritis is excellent. The author gives a follow up of twenty-two of the patients for an average period of three years. A transitory arthritis is difficult to differentiate from a commencing tuberculous infection of the joint. Clinically the two may be identical and remain so for days or even weeks. The roentgenogram is negative in a transitory arthritis except in the type due to a well defined neighboring bone focus but a negative roentgenogram does not absolutely exclude tuberculosis. As a matter of fact the roentgenogram is seldom absolutely negative in tuberculous arthritis when first brought for examination. Of the fifty-six children coming under treatment for early tuberculous arthritis of the hip there was only one whose roentgenogram at that time was absolutely negative. All the others showed bone atrophy about the affected joint most of them with loss of the joint space as well and many with bone

destruction already progressing. With a completely normal roentgenogram the diagnosis should be transitory arthritis rather than tuberculous. The earliest stages of a virulent pyogenic epiphysitis or pyemic joint may show a negative roentgenogram, but the differentiation of these from a transitory arthritis cannot be long delayed on both clinical and roentgenologic grounds. The roentgenogram in pseudocoalgia will seldom be so near to the normal that differentiation from a transitory arthritis will give rise to difficulty. All doubtful cases of arthritis in childhood must be watched carefully and treated like an arthritis that is likely to be progressive.

Anaerobic Streptococci and Puerperal Fever—Colebrook and Hare isolated anaerobic streptococci from the blood in forty cases of puerperal infections during the last four years. In the same unselected group of cases of puerperal fever there have been sixty-two which gave a growth of *Streptococcus pyogenes* from the blood. In only two cases were *S. pyogenes* and the anaerobic varieties present together. These anaerobic organisms rank second only to the group of hemolytic streptococci as causative agents of puerperal infection. In performing a blood culture the authors obtained 4 cc. of blood from the patient using 2 cc. for aerobic and 2 for anaerobic cultivation. One of the latter two was inoculated into Lepper and Martin's minced-meat-broth medium under petrolatum; the other was inoculated into a liver digest trypsin medium under a petrolatum seal. The authors' experience with this blood culture routine has confirmed the view previously stated by Colebrook that the use of fluid mediums for the isolation of these organisms from the blood is preferable to the method of long agar slant cultures. Two types of anaerobic streptococci or one type and some other organism are frequently present at the same time in the circulating blood. *Streptococcus pyogenes* is seldom associated with anaerobic streptococci in multiple blood infections. Anaerobic streptococci unlike *S. pyogenes*, *S. viridans* and other aerobic varieties are unable to multiply freely in human blood or serum but when the all-alk reserve of the serum is abolished or reduced or when the antitryptic power of the serum is neutralized they grow abundantly. Acidification of the serum favors the growth of other quite unrelated bacterial species e.g. *Staphylococcus* and *Streptococcus pyogenes* and *Bacillus coli*. The serous discharges from the uterus after the third day of the puerperium are found to have a much reduced all-alk reserve or actual acidity and a loss of antitryptic power such as will readily account for the profuse growth of the anaerobic streptococci and which is responsible for the offensiveness of the lochia in infected cases. It is highly probable that owing to the ischemia of the uterine wall during the first week of the puerperium its tissues are in a state of acidosis thus favoring the proliferation of many bacterial types and especially of the anaerobic streptococci.

The authors suggest that conditions of local acidosis may play an important part in favoring bacterial infections, quite apart from the puerperal state. Biochemical and serologic tests have not, up to the present, served for differentiation of the anaerobic streptococci. It is probable that they are a number of serologically distinct types.

 *Polymorphonuclear Lymphocyte Ratio at an Altitude of One Thousand Seven Hundred and Fifty Feet A. D. Stammers—p. 335

Action of Ether on Sympathetic System—According to the experiments of Bhattacharya and Burn, ether stimulates the sympathetic system, as shown by the following observations on decerebrate or spinal cats from which the suprarenals were removed. Ether causes (1) contraction of the spleen, (2) immediate inhibition of the intestine, (3) inhibition of the uterus of the virgin cat, and (4) rise in heart rate. The stimulus is applied within the central nervous system for the effects are not seen in the fully pithed animal, although a gradual intestinal paralysis may occur. The effect on the spleen in the decerebrate animal is abolished by nicotine. Ether usually has little effect on the blood pressure of the decerebrate cat without suprarenals, though it often causes an initial rise, after nicotine it causes a steep fall. When administered to the heart-lung preparation, ether greatly weakens the action of the heart, its effect is less than that of chloroform but is much more than is commonly supposed. The weakening of the heart does not result in a fall in blood pressure in the intact animal, because of the rise in arterial tone and increased output of epinephrine. There is no evidence that ether depresses the vasomotor system. Ether has no effect on the vessels of a limb perfused with blood. Chloroform and ethyl carbamate have the same action as ether.

Polymorphonuclear-Lymphocyte Ratio—Stammers states that an analysis of 171 cases of young healthy European adults, living at an altitude of 5,750 feet above sea level in the Transvaal, reveals a drop in polymorphonuclears of approximately 14 per cent and a rise in lymphocytes of about the same figure, as compared with the average normals (68.2 and 25.8 per cent respectively) for sea level. These observations are confirmed by another worker in the case of a group of eighty-one natives. So far as the differential leukocyte count has diagnostic value, the importance of recognizing these variations is obvious. The probable cause is the high degree of ultraviolet radiation which has been established for the locality of the investigation.

- *Dengue Fever with Hyperpyrexia Case M. Watson—p. 157
 Treatment of Malaria in Ceylon with Plasmoquine Quinine Compounds Critical Study of Fifty Cases E. C. Spaar—p. 158

Dengue Fever with Hyperpyrexia—Watson presents an instance of dengue fever complicated by hyperpyrexia in a girl, aged 13 months in whom the temperature rose to 105.6 F in the armpit, and a copious papular rash appeared on the chest, face and arms. Three days later desquamation commenced, just as in severe scarlet fever. There were no throat symptoms and no nasal catarrh. For the most part treatment consisted of the frequent application of cold sheets directly to the body. At times this acted slowly e.g. it took two hours to reduce the temperature from 106 to 102.4 F. The same day the temperature again rose to 105.6 F. the child was then laid

on a canvas bed and cold water (temperature about 80 F) poured directly over her. A full hour of this was required to bring the temperature down to 103 F, after which it fell to 100.2 F in half an hour. The instructions given were that, when the temperature rose above 102 F in the rectum, cold should be applied, and the result was that during a considerable portion of two days the child was in a cold pack or a cold bath. On the sixth day the child was decidedly brighter and on the seventh day the temperature fell to normal and continued so thereafter.

Nitrite and Electrocardiogram—Evans and Hoyle studied the effects of nitrite on the inverted T wave of the electrocardiogram in twenty-three patients. Nine patients with upright T wave were also tested for comparison. An amount of 5 minims (0.3 cc.) of amyl nitrite was inhaled, and from 1/500 to 1/2 grain (0.0006 to 0.005 Gm.) of glyceryl trinitrate was given in a tablet and chewed. The cases were placed in four groups according to the combination of leads which showed inversion of the T wave. In group 1 it was inverted in leads I and II, in group 2 it was inverted only in lead I, in group 3 it was inverted in leads II and III, and in group 4 it was inverted only in lead III. The deformed T wave was raised by the drug in seven out of nine cases in group 1, in two out of seven in group 2, in one out of four in group 3, and in one out of three in group 4. None of the patients with upright T waves, studied in a supplementary series, showed any significant changes. Inversion of the T wave has received such prominence and is so important in relation to coronary disease and myocardial changes that the authors consider that its modification, which they have seen produced by nitrite, may contribute to the elucidation of T wave inversion. It is surprising that a change heretofore reckoned as a prolonged one should vanish in a moment with nitrite. An increased blood supply in the periphery of the affected portion of the myocardium can account for the correction of a deformed T wave, which must therefore not be regarded as an irreversible abnormality. They believe that elevation of the inverted T wave by nitrite in patients with angina is determined by the relief of myocardial ischemia and further observations may show that the fixed T wave and the one elevated by nitrite bear a different significance, and that this may prove to be a measure of the efficiency of the collateral circulation round a damaged portion of the cardiac muscle.

*Immobilization of Lung by Alcoholization of Phrenic and Intercostal Nerves A Rodet—p 100

Immobilization of Lung by Alcoholization of Phrenic and Intercostal Nerves—Rodet states that immobilization of the lung or at least arrest of the evolution of pulmonary lesions can be accomplished by action on the innervation of the thorax, without bloody intervention. He reports two cases in which alcoholization of the phrenic nerve was used with favorable results. The method followed consists in first testing the patient's susceptibility to a solution of procaine hydrochloride by an injection into the epigastrium and then in anesthetization followed by alcoholization. The anesthesia is produced by injection of 2 cc of a 2 per cent solution of procaine hydrochloride at the diaphragmatic point (Gueneau de Mussy), the needle being passed obliquely upward and behind the junction of the seventh and eighth costal cartilages. Following this, 15 cc of 60 per cent alcohol is injected by inserting the needle 5 centimeters below the base of the xiphoid process and 5 millimeters to the side of the median line and directing it obliquely upward so that it reaches the insertions of the diaphragm behind the cartilage of the seventh and eighth ribs. Intense pain, in one case in the neck and in the other case in the shoulder, immediately after injection of the alcohol indicated that the phrenic nerve had been reached. The first patient had a large lesion of the left lung of six years' duration with large adhesions of the base. The first injection of alcohol produced a rapid defervescence. After a second injection following a cold with renewed fever, the patient remained apyretic. Expectoration was greatly diminished and the tubercle bacilli in the sputum became rare. The patient's general condition was so improved that she refused successive alcoholization of the intercostal nerves to complete the result. The second patient had a severe ulcerating unilateral lesion. Alcoholization of the phrenic nerve produced an immobilization of the left apex lasting a few months, and alcoholization of the intercostal nerves is now in progress. The latter method has been recommended as the method of choice when pneumothorax is impracticable because of adhesions provided it is used for two years and the injections are renewed every three or four months. It is less painful than alcoholization of the phrenic nerve and may be sufficient in itself.

*Nonspecific Anergy to Tuberculin E Frommel A Sierro and W Bachmann—p 1218

Nonspecific Anergy to Tuberculin—Frommel and his associates noted that the diseases in which a decreased resorption time of the skin has been demonstrated by the McClure-Aldrich test are the same ones in which an anergy to the intracutaneous tuberculin tests is said to exist. To test the hypothesis that the anergy to tuberculin is related to the decrease in resorption time of the skin they simultaneously performed the McClure-Aldrich and the intracutaneous tuberculin test on four groups of patients: patients exhibiting edema at the moment of the test; patients with nervous diseases; patients with hepatic disease and a few patients with typhoid or manifest tuberculosis. They used 0.2 cc of serum with 0.85 per cent of sodium chloride for the McClure-Aldrich test and 0.1 cc of a 1:1000 solution of old tuberculin for the other test. In all four groups the intracutaneous reaction to tuberculin was with a few exceptions parallel to the resorption time of the wheal and inversely proportional to the degree of cutaneous infiltration. When the time of resorption was greatly reduced the intracutaneous reaction was aborted when the resorption time was only slightly decreased the intracutaneous reaction occurred but was retarded or weak and when the McClure-Aldrich test gave a normal response the intracutaneous reaction was typical. The results indicate that the power of resorption of the skin plays an important part in the failure of the intracutaneous reaction to tuberculin. The authors sug-

gest that the failure of the intracutaneous reaction is not due to a specific serologic or tissue anergy but to certain physico-chemical factors having no specificity.

Treatment of Acute Purulent Arthritis of Large Joints G B Culmone—p 215
*Insulin and Gastric Chemistry E Filla and O Del Piero—p 222
Treatment of Essential Facial Spasm A M Dogliotti—p 228

Vegetating Aortic Endocarditis—Casanova and D'Ignazio describe a case of vegetating endocarditis of the aortic valves, developing during the course of a brucellosis in a young patient without history of previous disease. The isolation of *Alcaligenes melitensis* in pure culture from the blood and from the endocardial vegetations together with the results of histopathologic examination of sections of the vegetations and the general course of the disease allow the authors to affirm positively the melitococcic origin of the endocarditis.

Insulin and Gastric Chemistry—Filla and Del Piero have demonstrated on normal persons and on those suffering from impairment of the gastric function that, following injections of insulin, a hypersecretion of acid from the stomach takes place simultaneously with a reduction of the rate of glycemia. According to the authors, this hyperchlorhydria is not dependent on the direct action of insulin, which has been compared to histamine by other authors because of its action on the stomach, but is the direct exponent of the hypoglycemia due to insulin and of all the other conditions involved in the hypoglycemic syndrome. The gastric secretion is deemed one of the most important of these conditions as the earliest and most sensitive indicator of the hypoglycemia.

*Reaction of Henry in Serologic Diagnosis of Malaria M Biasiotti—p 557

Serodiagnosis of Malaria—Biasiotti applied Henry's serum reaction to 201 specimens of blood of which 154 were from patients with primary malaria and 47 from patients with recurrent malaria. The technic consists of preparing the melanin for melanoflocculation by removing the crystalline lens from the eyes of oxen, scraping the choroid and collecting the melanin together with the gelatinous liquid of the vitreous. To this is added twice the amount of distilled water and the whole is thoroughly mixed after which a 1:200 solution of formaldehyde is added and the mass is left standing for twenty minutes. It is next filtered through tightly packed glass wool and centrifugated in a sterile tube for five minutes at 4000 revolutions per minute. The blackish liquid that remains on the surface is decanted collected in a sterile container and preserved on ice. It is best to wait one month before using the prepared melanin because of modifications of opacity that occur in the original solution. The author recommends that the containers be shaken once a week in order to keep the melanin in fine suspension. Three dilutions are made from the original emulsion of melanin: one of 1 cc of melanin with 9 cc of distilled water, another of double the dilution of the first, and another of 1 cc of the first dilution with 9 cc of a saline solution at 3 per thousand. The tubes are shaken placed in an incubator at a temperature of 37°C for from two to four hours and left for fifteen minutes at room temperature. Reading is made three hours after the beginning of the reaction. Observations can be made with the naked eye. For iron flocculation 1 Gm of iron albuminate is dissolved in 600 Gm of bidistilled water and the solution is poured into sterilized glass ampules. The tubes of iron flocculation are prepared by adding 1 cc of the prepared iron solution to 0.2 cc of serum. The tubes after having been shaken are left in an incubator at 37°C for one and a half hours and then half an hour at room temperature. Reading is made two hours after the beginning of the reaction. In positive serum particles of the precipitate

vary in size according to the tubes used and in strong reactions, the precipitate is found at the bottom of the tube. Considering that melanin flocculation is more sensitive than iron flocculation, Henry advises that to six tubes of melanin only one or two tubes of iron flocculation be added. Of 154 specimens of primary malaria, 125 showed positive results. Of forty-seven specimens of recurrent malaria forty-one were positive. In twenty-five specimens taken from normal individuals, the reaction was completely negative as it was in twenty-five other persons with various acute and chronic diseases other than malaria. The author concludes that Henry's reaction is highly specific and sensitive and deems it valuable in laboratory determination of chronic latent and primary malaria and in splenomegaly of uncertain origin.

*Gastric and Duodenal Ulcer and Their Surgical Treatment A. Puccinelli—p. 1326

Surgical Treatment of Gastric and Duodenal Ulcer—

According to Puccinelli the clinical entity of ulcer is based on symptoms due to anatomopathologic lesions such as hemorrhages, perforations and pains caused by the ulceration at the nerve endings of the area involved. Other subjective and objective symptoms found in the morbid picture of ulcer do not characterize the ulcer but express a lack of equilibrium in gastroduodenal function constituting a syndrome apart which may be called gastroduodenal dyspepsia. Gastroduodenal dyspepsia may be secondary to an abdominal disease such as appendicitis, cholecystitis and other lesions of inflammatory and toxic nature; it can be ascertained also in a recurrent form manifested by accesses that are often seasonal. This gastroduodenal dyspepsia whether secondary or recurrent renders the stomach and the duodenum particularly sensitive and creates conditions facilitating the appearance of ulcerative processes. The treatment of gastroduodenal ulcer must be based on supposed causes more than on symptoms and must seek to eliminate the ulcerative factor by extirpation and cure. Gastroduodenal dyspepsia should be surgically treated if its causes can be suppressed thereby (appendicitis, cholecystitis and so on) but must be medically treated when the causes disappear or are supposed to reside in alterations of metabolism or to be of other nature. In the medical treatment of ulcer the author deems conformation to the gastric rhythm more important than the quality of the food given to the patient. The treatment by indirect action based on pepsin, benzoate and other medicaments has a temporary beneficial effect but sometimes no effect at all. The symptomatologic surgical treatment of dyspepsia has no logical basis because its real character is unknown; only direct signs of an ulceration offer surgical indication. Surgical treatment of ulcer promises the best curative results when it is radical as in emergency operations but the conservative and corrective operations (gastroduodenostomy, pyloroplasty and gastrojejunostomy) have precise indications and offer good results.

Etiopathogenesis of Erythema Nodosum J. Dominguez Luque—p. 293
Present Status of Etiologic Problem of Scarlet Fever A. Ruiz Diez—p. 307

Sedimentation Test in Early Diagnosis of Whooping Cough—On the basis of forty-four cases studied during an epidemic of whooping cough Sainz de los Terreros draws the following preliminary conclusions: 1. During the first two weeks of the disease, i. e. during the stage of catarrh, there is in the majority of children a retardation of the sedimentation speed contrary to what is found in bronchial and bronchopulmonary diseases in which there is no infection with Bordet's bacillus. 2. This retardation of the sedimentation speed disappears at times after the second and generally after the third week and changes to an increase of the sedimentation speed which is the rule in the majority of infectious diseases. 3. Differences found from case to case and even in the same patient are due to plasmatic changes which should be studied in order to arrive at safe conclusions.

Vascular Tonus and Cerebral Cortex—Popper reports two cases illustrating the fact, pointed out by Pal, that lesions of the cerebral cortex may result in persisting differences of vascular tonus. In such cases comparative bilateral palpation of the radial arteries shows the artery on the side contralateral to the cortical lesion to be softer and sometimes wider than the other one. This is due to a loss or decrease of tonus through disturbance of the central tract for tonic innervation of the vascular wall. The tract for the tonic innervation of the blood vessels is in immediate proximity to the motor tracts and extensive lesions of the latter regularly involve the former. However, there may be lesions especially in the region of the basal ganglia which cause a decreased tonus of the arteries without causing paralysis. Occasionally, a difference in vascular tonus persisting for years is the sole remaining sign of a hemiplegia that has receded. Not only a pathologic process evolving within the cortex but one spreading from the meninges to the cortex may result in paralysis and reduced arterial tonus. In the two cases reported a difference in the vascular tonus of the radial arteries existed in the one case forty-five years and in the other case thirty-five years after the occurrence of a meningitis. These persisting differences in vascular tonus following cerebral processes demonstrate the significance of the cortical regulation of vascular tonus and may help to throw light on the diseases involving hypertonia of the arteries.

Gastric Disturbances in Liver Echinococcosis—Maluschew reports two cases of liver echinococcosis with severe gastric complications making a total of six cases seen by the author. In one of the cases reported there was a severe compression stenosis of the duodenum with high grade dilatation of the stomach. In the other case there was an ulcer on the upper edge of the pylorus which was joined to the gall bladder by adhesions at this point and drawn upward, and moderate dilatation of the stomach with severe dilatation of the upper horizontal portion of the duodenum. The author stresses the importance of a thorough roentgenologic examination of the stomach in echinococcosis of the liver.

Meningitis in Alcaligenes Abortus Infection—Bingel and Jacobsthal, after reviewing the rather small literature on neurologic complications of Alcaligenes abortus infections, report their observations on a patient in whom meningitic symptoms developed. The case is noteworthy because it was possible for the first time to detect Alcaligenes abortus in the

cerebrospinal fluid This demonstration of *Alcaligenes abortus* together with the positivity of the complement fixation reaction and of the agglutination reaction in the cerebrospinal fluid seems to justify the assumption of a meningitis caused by *Alcaligenes abortus*. The authors are as yet not in a position to say anything about the prognosis of this form of meningitis. It takes a subacute course and the patient is still under observation.

Circulation Following Removal of Suprarenals—Langsdorf observed in experiments on rabbits that the removal of both suprarenals produced on the heart and the vessels signs of a decreased sympathicotonia. The rest values of the pulse rate and of the blood pressure do not necessarily show this reduction and both may be unchanged compared to the normal, but the capacity to increase is noticeably reduced in the pulse rate as well as in the blood pressure. The heart develops muscular hypotrophy.

Biliary Colic on Allergic Basis—Von Eiselsberg describes the histories of three patients in whom certain foods such as milk, eggs and tomatoes, produced biliary colic. These foods did not produce this effect when, before eating them the patients were desensitized by the administration of small doses of homogeneous peptones (propeptones according to Luthlen Urbach). The author points out that these case reports corroborate the theory of an allergic genesis of some cases of biliary colic and show the way for the therapy of such cases.

Edema in Diabetes Mellitus—Stoltz aims to show that not insufficient utilization of food but rather an inadequate intake of nourishment is responsible for the diabetic edemas. He points out that many authors are of the opinion that the food supply of diabetic patients should be as restricted as possible. If edema develops they generally restrict the sodium chloride intake just as is done in patients with renal disease and occasionally diuretics are administered. However the author as well as other investigators have found that sodium chloride cannot be dispensed with in the treatment of diabetic edemas. He observed cases of diabetic coma in which the administration of insulin, water and sugar was not effective until after the patient had been given from 5 to 10 Gm of sodium chloride. He was induced to try this sodium chloride medication because the comatose state of diabetes greatly resembles the intoxication of nurslings. The loss of weight in these nurslings is effectively counteracted not by water but by sodium chloride more specifically by a solution of 0.5 per cent of sodium chloride and 0.5 per cent of sodium bicarbonate and in

the most severe cases only by giving nourishment particularly buttermilk. The author ascribes to the use of a more or less unrestricted diet the fact that edema is rare in the diabetic children in his clinic. The state of the diabetic patient and that of the nursling having severe diarrhea are similar in that both have to give off large amounts of fluid and that the tissues are attacked after all the free water has been eliminated. The author describes two cases illustrating the importance of an adequate food intake for the prevention and treatment of edema and he reaches the conclusion that the edema in a diabetic patient is really the edema of a cachectic patient, and that although such edemas can be checked by sodium chloride restriction and eventually by diuretics such treatment is of little avail for only the treatment of the underlying cause the cachexia, will improve the tissues and restore their normal water binding power.

A Lid Symptom in Nurslings—Epstein observed in a group of neuropathic nurslings a lid symptom resembling Dalrymple's sign or von Gräfe's sign. The lid symptom gives the nursling a somewhat agitated, scared expression so that the author designates it as the 'wild glance'. The symptom was rarely uninterruptedly present, in general it developed temporarily and its intensity was subject to fluctuations. It was most severe when the nursling showed nervous alterations or when disturbances in the general condition existed. The lid symptom of the 'wild glance' was often noted at the onset of alimentary toxicosis.

Irradiated Ointments J Arendt—p 1137

Surgical Treatment of Tonsils During Childhood—Nadoleczny thinks that hyperplasia of the tonsils necessitates tonsillectomy only in rare cases, that is, only when it is the cause of respiratory disturbances and of considerable alterations in the tonality of the voice. Suppurative inflammations of the tonsils are comparatively frequent during childhood and are as such no indication for the removal of the tonsils, but operation may be indicated if the condition becomes chronic. Peritonsillar abscess likewise is no absolute indication for operation but acute septic diseases necessitate removal of the tonsils. In acute articular rheumatism preceded by tonsillitis tonsillectomy is often helpful but its value is doubtful in muscular rheumatism neuralgia and neuritis. The operation is more promising in acute glomerular nephritis and in embolic focal nephritis as long as nephrosclerosis has not yet developed. In chronic nephritis and in arthrostatic albuminuria tonsillectomy is ineffective. Opinion is still divided about the advisability of tonsil operations in chorea minor although operation is helpful in some instances. In severe cases of endocarditis and of myocarditis there is hardly any hope but in recurring or in polyarthritic endocarditis tonsillectomy is often effective. Glandular fever is often favorably influenced by tonsillectomy and by adenotomy, and diphtheria bacillus carriers have also been successfully treated by tonsillectomy. However tonsillectomy is no protection against diphtheria or against Vincent's angina because the nasopharynx, the fauces and the nose may still become involved. The decision about the advisability of the removal of the pharyngeal tonsils is generally less difficult than is that of the palatine tonsils but the author thinks that here likewise surgery has been overemphasized. He advises that the children be carefully examined before adenotomy is resorted to and he says that rhinoscopy is possible even in comparatively young children. In discussing the methods of tonsillar operations he points out that tonsillectomy is generally more effective than tonsillotomy. Since every operation injures the psyche of the child the operation should not be done simply on general indications but each case should be studied carefully as an unnecessary operation is detrimental not

only to the patient but also to the physician and the medical profession, for it destroys the confidence of the patient

Changes in Articulations of Vertebral Processes—Lange found that every deformity of the vertebral column is characterized by changes in the articulations of the vertebral processes. These changes are far in excess of the physiologic motility, and sooner or later the abnormality of the articular space becomes fixed. A part of the articular space may become wider and another part may be narrower or entirely obliterated, or the widening or narrowing may involve the entire space uniformly. The result of the positional changes is that the joints show wear prematurely and in arthrosis deformans develops early. The author stresses that arthrosis deformans is to be strictly differentiated from and not to be confused with spondylosis deformans of the bodies of the vertebra, the latter being caused by a degeneration of the intervertebral disks. The law of functional overburdening has the same significance for the development of the arthrosis deformans in the articulations of the vertebral processes as it has for the development of arthrosis deformans in the joints of the extremities, that is, the arthrosis commences at the sites of the greatest mechanical burdening, and in advanced cases the most pronounced changes exist likewise at these sites. The author discusses the development of arthrosis deformans in various disorders of the vertebral column, in scoliosis, in kyphosis and in vertebral fractures. In the latter disorder the development is particularly rapid. The studies on the pathology of the vertebral joints also indicated the cause of the backaches that sometimes occur in corpulent women with increased sacral concavity. It was observed that the articular spaces of the lumbar vertebrae had become wider and that the articular processes had become somewhat dislocated. This makes it understandable that these women complained of fatigue or of pain in the sacral region and that the wearing of a support gives them considerable relief.

Changes in Bacterial Flora Following Gastric Resection—Following gastric resection (Billroth I and II) on dogs with artificial fistulas in various segments of the small intestine, Hertel and Sartorius found an increase of insufficiently digested food, an increased and abnormal bacterial flora and evidence of increased decomposition processes in the small intestine. The increased bacterial flora contained, besides abundant colon bacilli, a large number of the gram-positive organisms typical of the flora of the large intestine. A manifold increase of indole in the upper half of the small intestine was observed, it was greatest after consumption of meat, less after consumption of milk and whey, and least after the consumption of sour milk. This is an indication of the increased production in the small intestine of decomposition products usually formed chiefly in the large intestine. Increased resorption of these toxic decomposition products and of bacterial toxins by the highly resorptive small intestine favored by mechanical and chemotoxic injury to the intestinal wall, may be the cause of the dyspepsia enteritis anemia and general disturbances sometimes seen after gastric resection. Following gastric resection a limitation of food proteins and substitution of a milk and vegetable diet are recommended to withdraw from the pathologic intestinal flora the nutrient medium supplied by the insufficiently digested protein.

External Otitis H Frey—p 951

Serologic and Allergic Reactions of Scleroma—After discussing the progress of the serologic diagnosis of scleroma by means of complement fixation and agglutination reactions, Neuber reports favorable results with allergy reactions. The antigen was prepared by Adam's method. A suspension of scleroma culture (one loopful to 1 cc of distilled water) is desiccated and pulverized. To this is added 0.5 cc of sulphuric ether, which is evaporated over the water bath. The residue is dissolved in phenolized physiologic solution of sodium chloride in the proportion of 1:20. Intracutaneous tests gave excellent results from the standpoint of specificity. In most cases twenty-four hours after vaccination with 0.1 cc of the scleroma antigen, an edematous hyperemic areola, 1 cc in diameter appeared at the site of vaccination and usually gave way to a sharply circumscribed infiltration after six or eight days. Around the vaccination sites of heterologous antigens, such as those of *Bacillus mucosus capsulatus*, *Bacterium ozaenae* and others temporary hyperemic areolae frequently appeared within the first twenty-four hours, but they disappeared at the time when the specific allergic reactions exhibited a particularly strong development. The specificity of the intracutaneous allergic reactions with antigen derived from *Bacterium rhinoscleromatis* is especially valuable in cases in which the disease is located in parts of the body not readily accessible to clinical and microscopic examination or in cases in which facilities for performing serologic reactions are not available. The author points out that the favorable therapeutic results obtained with homologous and particularly with autogenous vaccines in cases of scleroma forcibly demonstrate the etiologic role of *Bacterium rhinoscleromatis* in this disease.

- *Prevention and Treatment of Disorders of Spinal Cord in Pernicious Anemia E Meulengracht—p 819
*Treatment and Diagnosis of Pernicious Anemia A Norgaard—p 825
Senile Marasmus I. C. Stage—p 827

Disorders of Spinal Cord in Pernicious Anemia—Meulengracht has found desiccated stomach more effective than liver or liver extract in pernicious anemia, especially in protecting against myelopathic symptoms and in their treatment. He emphasizes that the myelopathy is not an inevitably progressive disorder but may be checked under certain conditions improved or apparently cured. He cautions against under dosage in pernicious anemia and points to the danger of reducing the dose during a period of remission, when he has seen grave myelopathy develop in two weeks. As high a maintenance dosage as possible is urged such as from 20 to 30 Gm of desiccated stomach and from 200 to 300 Gm of whole liver, daily, and in threatening or developed myelopathy he would give from 33 to 40 Gm of desiccated stomach daily, possibly with supplementary subcutaneous injections of injectable liver extract.

Pernicious Anemia—Norgaard asserts that heretofore too small doses of liver preparations seem to have been used in pernicious anemia and that stomach preparations seem generally to be more effective than corresponding amounts of liver preparations. Absolute assurance of recovery or continued good effect can hardly as yet be given, even with massive doses of liver and stomach preparations, although the specific effect is undoubted. As a rule specific treatment with liver or stomach should not be started before the diagnosis has been verified by the history and by examination of the blood, the gastric secretion, the mucous membrane of the tongue and the nervous symptoms. After the diagnosis has been made, treatment should be massive.

OCTOBER 7, 1933

ORGANIZATION OF THE ANESTHESIA SERVICE OF THE GENERAL HOSPITAL

CHAIRMAN'S ADDRESS

ALBERT H. MILLER, M.D.

PROVIDENCE, R. I.

Under the apprentice system of medical education as practiced in the past generation, instruction of his students in methods of administration of anesthetics was an important duty of the preceptor. The preceptor performed this duty well, supervising the work of the students until it was done to his satisfaction. When, at the beginning of the present century, the apprentice system went out of vogue and the duties of the preceptor were undertaken by the medical school, provision for instruction in anesthesia was generally neglected. Medical graduates, entering hospitals without instruction or interest in this work, administered anesthetics in a careless and inefficient manner. Search for a solution of the problem of satisfactory anesthesia resulted in the employment of technicians instructed and supervised by some member of the surgical team who had been trained under the former regime. It was early predicted that, after a single generation had passed, this plan would result in a lack on the surgical team of any member competent, from training and experience, to supervise the administration of anesthetics. This is the condition that now confronts the medical profession.

NEED FOR AN ANESTHESIA SERVICE

With few exceptions, medical schools offer no instruction in anesthesia and their teaching hospitals provide the interns with no opportunity for practical experience in the use of anesthetic agents. The outlook is especially dark from the surgical point of view. The present hospital intern is the surgeon of the future. During the years spent in school and hospital he has developed an aseptic conscience which automatically guards him from faults in aseptic technique. A similar appreciation of the powers and limitations of anesthesia is required for the best surgical work.

The surgeon should be competent to make and to evaluate the preoperative examination, to assess the operative risk, to make an intelligent choice from the anesthetic agents, to appreciate the limitations of the chosen agent and to recognize the influence of the anesthetic in the causation of postoperative complications. Lacking this knowledge, he may decide to allow

his technicians to use any agent with which they are familiar, he may discard general anesthesia and make extensive use of spinal anesthesia whether or not indicated, or he may extend the use of regional methods regardless of the feelings of his patients, blaming as uncooperative those who complain of an excess of pain. In the presence of postoperative hemorrhage or infection, he will delay while searching for suspected anesthetic sequelae. When death results from an overdose of the anesthetic, he will attribute the fatality to cardiac failure or surgical shock.

INSTRUCTION OF INTERNS

The medical graduate, before he enters the hospital, has mastered physics, chemistry and the higher mathematics. He has studied anatomy, physiology, physiologic chemistry, pharmacology and pathology. He is fundamentally trained in medicine, surgery, obstetrics and neurology. These studies form the essential basis for intelligent work in anesthesia. To complete a satisfactory course, this knowledge must be collated from the anesthetic standpoint, some features must be emphasized, and opportunity must be afforded for experience in the use of anesthetic agents under skilled supervision. While this training is of value to every medical graduate, it is essential for those who contemplate practice in any one of the surgical specialties.

So large is the proportion of medical graduates who have had no preliminary instruction in anesthesia that the hospital must provide both theoretical and practical teaching for its interns. The system which is here described has been in operation at the Rhode Island Hospital for the past thirty-two years. The course of instruction in anesthesia includes didactic lectures, demonstrations of methods by the staff of anesthesiologists, and administration of anesthetics under supervision. Experience in administration of anesthetics may be gained at any period in the intern's course but preferably not until he has had time to become accustomed to hospital life and routine. The student begins with the simplest methods, straight ether by an open method and nitrous oxide-oxygen for short operations not requiring relaxation. At first his work is constantly supervised, but as he becomes more skillful he may be certified as competent to administer first one and then another agent without immediate supervision. During his anesthetic service the intern should have an opportunity for the use of every anesthetic agent and method that is in routine use in the hospital. Several months is required for this experience.

The aim of the lecture course is to review the features of basic science that have special bearing on the subject of anesthesia, to teach the fundamental facts essential to the successful administration of anesthetics, to bring out recent advances in anesthesia and

especially to arouse the interest of the student in this subject. For this purpose the lecturers recite interesting cases and personal experiences and may illustrate with lantern slides and motion pictures. Staff lectures provide an important phase of the intern's training and are already provided by 460 of the 696 hospitals approved for interns. The lectures on anesthesia may readily be made as interesting as those coming from any department of the hospital.

SUGGESTED LECTURE SUBJECTS

The following is a list of subjects suggested for lectures

The various anesthetic agents, their physical properties pharmacology and physiologic effects

The hypnotics

The examination of the patient and the evaluation of surgical risk.

The choice of the anesthetic

The preparation of the patient

Methods of administration and modifications indicated for different operations

The signs of anesthesia

The signs and effects of anoxemia and oxygen excess

The signs and effects of carbon dioxide deficiency and excess

Blood pressure, effects of shock and hemorrhage

Basal metabolism

Effects of posture during and following operation

Spinal anesthesia

Regional anesthesia

Accidents and sequelae of anesthesia

Resuscitation

After-Care

Obstetric anesthesia.

Dental anesthesia

Utility and technic of oxygen therapy

Applied physiology of the circulation and respiration

Reflex nervous activity

An outline of the history of anesthesia may be given as a single lecture or used in parts as an introduction to several lectures. Some of the topics furnish material for several hour lectures

PERSONNEL OF THE STAFF OF ANESTHETISTS

The chief anesthetist is a member of the hospital staff and has the same authority in his department as the medical and surgical chiefs have in theirs. His appointment is made with the approval of the surgical chief and his department must be managed with sufficient tact to avoid friction with the members of other services. The physician who is competent for this position may well have had some experience in the practice of medicine and surgery in addition to extensive experience in the administration of anesthetics. To keep abreast of the latest developments in his specialty he should study the literature, attend the conventions of anesthetists and keep in touch with the work in anesthesia that is being done in his own and in other centers. He may be a full time officer or may devote a part of his time to administration of anesthetics for private patients while exercising general supervision over his department in the hospital. In any case, he will need one or more assistants to carry on the work in his absence. The chief anesthetist is responsible for administration of anesthetics in the hospital in a manner satisfactory to the surgical chief. The assistant anesthetists have privileges and duties similar to those of the chief but subject to his control.

One or more resident anesthetists may be chosen from recent graduates of the hospital who show special

aptitude for anesthetic work. They supervise the work of the interns under the direction of the chief and administer anesthetics in the more difficult cases. They are interested in working with new agents and in developing new methods. They should have oversight of the preoperative examination and the assessment of operative risk and of the postoperative follow up system. Fourteen hospitals already employ resident anesthetists. Whether they choose to specialize in anesthesia or to take up one of the surgical specialties, the time spent as resident anesthetists will not have been wasted.

EXAMINATION OF PATIENTS

Under the guidance of the visiting and resident anesthetists, the one who is to administer the anesthetic should make the preoperative examination and assess the operative risk. This is done preferably on a day previous to the operation. The results of the examination must be recorded and the record made available in the operating room at the time of operation. It happens too often that examinations made at considerable expense to the hospital are recorded and never seen again. To avoid expensive and distressing errors, the nature of the proposed operation should be carefully recorded, with special attention to which side of the body is affected, as in contemplated eye enucleation, hernia operation or breast amputation.

The student should develop sufficient interest in anesthesia to compel him to attend to this duty rather than to follow minutely the steps of the operation. His interest should lead him to visit the patient frequently during the days following and to record the results of his work.

RECORDS OF ANESTHESIA

Beginning with his first anesthesia, the student keeps a record chart of each administration. This record fixes his attention, provides a graphic view of the patient's condition throughout the operation and opens to view an interesting field for study. The record chart shows the anesthetic agent and the method of administration, the anesthetic dosage recorded at frequent intervals, salient features of the operation, operating room conditions as to temperature and humidity, and the position of the patient with special note of changes in posture. The patient's condition is noted at intervals of from five to ten minutes: the pulse rate, the rate and character of the respiration, the systolic and diastolic blood pressure, the condition of the skin as to color, temperature and moisture, the presence of mucus and of tears, and the state of those reflexes by which the anesthetic zones are minutely gaged. The time when the administration is started and the time when the operation commences and when it is ended are carefully noted. The duration of the anesthesia and of the operation may readily be reckoned and need not be recorded.

The fallacious idea that each hospital should devise record sheets for its individual needs has resulted in much wasted effort in preparing record sheets to fulfill supposedly peculiar conditions. As record sheets are not subject to climatic variation, the chart that is best in one part of the country will be equally efficient in another district. The scientific value of medical records depends less on the character of the individual sheets than on the method by which they are filed and indexed. The isolated individual record loses much of its value as soon as it is completed. Properly filed and indexed, it becomes a unit in a repository of scientific fact. With

the numerical system of filing, the anesthetic record sheet is filed with the rest of the history under the consecutive admission number. Indexing may be done on cards or in loose-leaf books. Under a given title at the head of an index card are listed the admission numbers of all cases falling under this title for a set period. The index may be very simple or may be expanded without limit. From the standpoint of anesthesia, the names of surgeons and of anesthesiologists, the operations, the anesthetic agents, the preliminary hypnotics and the post-operative complications and fatalities are practical titles for the index system. Filing and indexing of anesthetic records should be done by the record room clerks and frequently checked up by the visiting or resident anesthesiologists. A separate record system for each department of the hospital is extravagant and inefficient.

INHALATION THERAPY

Treatment with an excess of oxygen is one of the most valuable therapeutic measures. Resuscitation from the effects of deleterious gases is frequently demanded by the artificial conditions of modern life. When the emergency requiring oxygen therapy or resuscitation arises, the time for preparation has passed. Hospital authorities will consider their duty finished when they have provided expensive resuscitation apparatus, which in inexperienced hands is both inefficient and dangerous. Interns and nurses should be instructed in the operation of oxygen therapy and resuscitation devices and developed into efficient teams by frequent drills. From their familiarity with apparatus and methods of handling compressed gases, the staff of anesthesiologists is best fitted for this work. The anesthesiologists are also frequently called on by other departments for treatment of severe pain. The anesthesiologist knows no pain that he cannot relieve.

ECONOMIC CONDITIONS

In this country the greater number of anesthetics are administered by trained nurses. The work of the nurses with the routine methods that they have been taught is very satisfactory and sets a standard which the efforts of the interns have difficulty in surpassing. The nurses do not advance the art of anesthesia and from their lack of preliminary education in basic science cannot become competent to teach medical students and graduates. As the popularity of nurse anesthetists increases, the number of graduate anesthetists decreases. Jan. 1, 1932, there were 542 physicians in the United States who limited their practice to or gave special attention to anesthesia as a specialty. March 15, 1933, the number had diminished to 533, this with 6,000 hospitals and 30,000 surgical specialists. This condition is due not to a deficiency in the number of medical graduates nor to a lack of operations for which anesthesia is required but to the economic conditions under which anesthesia is practiced. Medical graduates who choose anesthesia as a life study must be supported either by a stated salary or from fees collected for anesthetizing in private cases. Many hospitals exploit nurse anesthetists, employed at a small salary, by charging for their services to private patients fees which are added to the income of the hospital. The more efficient the department of anesthesia becomes the greater is the temptation for members of the surgical staff to utilize the well-trained interns and nurses to administer anesthetics for private patients free of charge. Many physicians still refer operative cases to surgical specialists with an understanding that

the physician shall administer the anesthetic and collect a fee for this service. Knowledge of such practices lowers the morale of the staff of anesthetists and will ultimately destroy the anesthesia service, however well organized.

In a hospital in which the staff may treat private patients there should be a list of approved anesthetists, physicians at least as competent to administer anesthetics as are the interns and nurses. The anesthetists for all operations on private patients should be chosen from this list. Anesthetics should be administered by resident anesthetists, interns and nurses only in the ward cases for which the surgeon charges no fee.

CONCLUSIONS

The functions of an anesthesia service in a general hospital are to provide satisfactory anesthesia for the patients and to train the younger practitioners in the art of anesthesia. This training is requisite for recruiting the number of graduate anesthetists and for familiarizing the future surgical specialists with a subject that they will constantly encounter in their daily work. A department of anesthesia cannot be conducted without expense, a factor which must be met by the patient, the surgeon or the hospital.

OTORHINOLOGIC ASPECTS OF SCARLET FEVER

WITH PARTICULAR REFERENCE TO THE SINUSES

GORDON D. HOOPLE, M.D.

AND

LINUS S. CAVE, M.D.

SYRACUSE, N. Y.

This paper deals chiefly with a study of the sinuses in scarlet fever made at the City Hospital for communicable diseases at Syracuse. Interest in this study was aroused by the results of a few x-ray films which were taken in a group of cases of scarlet fever complicated by otitis media. In each instance, the x-ray films disclosed a sinusitis of more or less severity. From this small beginning a series of 292 cases was studied. X-ray films were taken of the sinuses of the patients in this group and were examined for evidence of sinusitis. Certain interesting findings were brought out, and these stimulated an interest for further investigation, so a second group, numbering 80 cases, was selected and a rather intensive study made. In this second group each patient on entrance to the hospital, was examined by the attending pediatrician (Dr. A. C. Silverman) and otolaryngologists (Drs. Hoople and Cave), and as soon as possible thereafter, an x-ray film was taken of the sinuses, which was interpreted by the attending roentgenologist (Dr. D. S. Childs). The findings of each man were recorded independently. The patients were watched during their stay in the hospital and just before discharge they were reexamined and x-ray films were taken. These findings make up the body of this report. In the first series (of 292 cases), no serious attempt was made to check clinically the roentgen findings but the results in this group brought out the advisability of such a

This study was made under the auspices of the Hendricks Research Fund of the Syracuse University College of Medicine.

procedure, hence the careful clinical check in the second series

The findings in the first series have been reported in some detail by Silverman¹ That there may be a proper background for a study of the second group, a summary of the findings in the first series is herewith presented The investigation of the first group was conducted during 1930-1931 To determine whether or not the cases of this group were representative as to age, sex and the season of the year, a comparison was made with the total number of cases in the city of Syracuse during this period

In table 1 it is seen that the total number of cases in Syracuse during the period was 1,205, and in this series, 292 The sex ratio was approximately the same, showing a slightly greater incidence in females in both groups Table 2 giving the number and percentage distribution according to age groups, shows a striking similarity between cases in the city and those in which x-ray films were taken, except for patients under 5 years In a number of cases at the hospital films were not taken because of the difficulty in obtaining cooperation and because the patients were too young

TABLE 1—Sex Distribution in Cases of Scarlet Fever and in Those in Which X-Ray Films of the Sinuses Were Taken

	Total	Male	Female	Ratio
Cases in city	1 205	579	626	1 1 081
Cases in which x ray films were taken	292	140	152	1 1 053

Table 3 shows the percentage comparisons, according to different periods of the year, between the cases in the city and those in which x-ray films were taken There is a fairly striking similarity between the two The bimensual percentage of cases in which x-rays were taken is somewhat coincident with the seasonal variance of scarlet fever

Before discussing the roentgen findings in this and the second group, some explanation of the terminology used seems advisable The roentgen findings were classified according to the shadow seen as follows clear, thickened membrane and retained secretion This is an arbitrary classification, and its limitations are

TABLE 2—Number and Percentage Distribution of Cases of Scarlet Fever and of Those in Which X-Ray Films of the Sinuses Were Taken, According to Age Groups

	Cases In City		Cases In Which X Ray Films Were Taken	
	Number	Percentage	Number	Percentage
Total	1 205	100	292	100
Under 5	185	15 4	28	9 6

realized X-ray films were designated as "clear" when no shadow could be made out in the sinuses This part of the classification is simple, but the second presents difficulties and can be questioned However, in both series here reported, x-ray films were included under the heading "thickened membrane" when there was a shadow in one or more of the sinuses, which shadow

was not dense enough to warrant the conclusion that retained secretion was present Finally, when a film showed an opaque shadow, the case was placed under the heading "retained secretion" (The roentgen findings in the first series have been reported by Childs, with the use of a different terminology The classification just described is used with his sanction)

TABLE 3—Number and Percentage Distribution of Cases of Scarlet Fever and of Those in Which X-Ray Films of the Sinuses Were Taken, According to the Time of Year

	Cases In City		Cases In Which X Ray Films Were Taken	
	Number	Percentage	Number	Percentage
Total	1 205	100	292	100
February-March	441	36 6	63	23 3
April-May	420	34 9	111	38 0
June-July	130	10 8	42	14 4
August-September	46	3 8	7	2 4
October-November	47	3 9	12	4 1
December-January	121	10 0	52	17 8

Table 4 is the most interesting one of the first series Ninety-one per cent of the total showed some shadow on the x-ray film, only 9 per cent showed all the sinuses clear The great majority of the shadows were interpreted as being due to a thickened membrane No attempt was made to check these findings clinically, by irrigation or by other methods Some of the shadows were fairly dense and might have included retained secretion At least the great majority of the cases showed a reaction in the lining membrane of the sinuses The sinus most frequently involved was the antrum Following this was the ethmoid and then

TABLE 4—According to Type (Designation of Shadow)

the frontal The sphenoid was excluded in the examination of the sinuses because of the extra effort in making this exposure and because such a goodly number were in the age group in which a reading would be of little worth

Table 5 shows an incidence of otitis media comparable to that in a number of reported cases There were 33 cases with otitis media among the 292 examined The incidence is 11 3 per cent Ross² has reported on 15 lists of otitis media in scarlet fever, and in most of these the incidence was greater than 11 per cent This table brings out the interesting fact that no ear showed purulent otitis media unless there was sinusitis evident by the x-rays on the corresponding side Conversely, in the cases in which the x-ray films were clear there was no incidence of otitis media In the great majority, 26 of 33 cases, both sides of the nose showed some shadow in the sinuses whether one or both ears were involved

COMMENT ON THE FIRST SERIES
The first series, of 292 cases of scarlet fever in which x-ray films were taken, showed a surprisingly

large number of patients who had roentgenologic evidence of sinusitis. This finding was higher than was expected by those conducting the study and called for a more complete investigation in which some attempt would be made to link together the clinical and laboratory evidence. This will be considered in the discussion of the second series. Further interest was aroused when it was found that there was no incidence of otitis media without the presence of sinusitis. This finding was further qualified by the observation that in every case of otitis media there was some involvement of the sinuses on the side of the lesion of the ear. These discoveries led our associates and ourselves to hope that they might be duplicated in another group of cases in which closer clinical observation was conducted. In this first group the cases had been selected primarily for the roentgen study, and the study was continued for a period of more than one year to observe any

seasonal variation which might be present. None having been found, save for the seasonal incidence of scarlet fever itself, the second study was begun immediately, and a group of 80 cases was observed.

Table 6 needs but little comment. The cases, as will be noted, were studied in the first three months of the year. The percentages in the age groups and the division between the sexes are not unlike those in the first series. The percentage of cases of the severe type was considerably less in this group—7.5 per cent against 20 per cent in the other—which offsets the influence that might be present by selecting these cases from the first fourth of the year. This is a factor

which should be considered, for in the first series less than 2 per cent of the severe type of cases showed clear sinuses.

Table 7 is interesting not only for the findings from the original x-ray film, but for those from the subsequent one. The first x-ray film was taken as soon as it was convenient after the patient entered the hospital. In the majority of the cases it was made shortly after the onset of the illness. A few of the patients did not enter

the hospital until a week or more from the beginning of the scarlet fever. The second x-ray film was taken at the end of the period of isolation, usually on the twenty-eighth or twenty-ninth day.

Twelve of the eighty patients showed a clear x-ray film at or near the onset of their illness. However, five of them showed involvement of the sinuses at a subsequent time, leaving but seven who showed clear

TABLE 7—Designation of Shadow

* Five of the originally clear sets were reported involved in subsequent roentgen examination.

sinuses throughout their illness. Thus, in the second series 91 per cent of the patients had roentgen evidence of sinusitis, which corresponds closely with the percentage in the first group.

Perhaps a more surprising finding is the result of the so-called "discharge x-ray" film. That so many should show involvement four weeks after the onset is enlightening. One immediately wishes to connect these findings with the clinical observations to determine the possible epidemiologic significance. This point will be discussed later in the paper. What should be noted here is that many of the patients who showed thickened membrane or retained secretion were not discharged at the end of the usual period of isolation. The discharge examination was more carefully made, and these cases were observed until there was no clinical evidence of further infection.

Before a comparison between the roentgen evidence and the clinical findings is made, it should be recalled

TABLE 8—Designation of Shadow, Clinical Examination

	Clinically Positive	Clinically Negative
Clear	12	7
Thickened membrane	61	46
Retained secretion	7	4

that the findings of the otolaryngologist and roentgenologist were recorded independently. The report of one was not read by the other until the findings of both had been placed on the patient's chart. This procedure gave interest to the comparison between the roentgen and clinical findings, which is given in table 8.

It is easy to understand that a clinical examination at any one time may not reveal sinusitis. All otolaryngologists have had this experience. Another examination a few hours later, or a day apart, may give the evidence for which one is searching. This is a possible reason why there are eighteen cases (fifteen in the group with thickened membrane and three in the group with retained secretion) in which the results of clinical examination did not support the roentgen evidence. On the other hand, there were seven cases in which the clinical evidence was such that the diagnosis of acute sinusitis appeared to be justified, yet roentgen examination of the sinuses reported them all clear. A more careful study of these cases, together with those which remained clear roentgenologically throughout their illness, is included in table 9.

It should be noted that the patients in the twelve cases which thus stood out because of clear x-ray films were with one exception 7 years of age or older. The

one exception was an interesting case. The initial infection apparently was mild, but a secondary attack of scarlet fever developed and the patient was desperately ill for many weeks. It has not been brought out in any table, but the percentage of clear sinuses in both series was much higher in the older age groups than in the younger.

In seven cases the x-ray films were clear on both the first and second examinations. In three cases clinical examination gave negative results, and in four, positive results. All but one of the patients were in the second

TABLE 9—Study of the Details of Patients with Clear X-Ray Films

or third decade of life. Seven cases were positive clinically but showed clear x-ray films on the first examination. The tonsils and adenoids were present in six of the seven patients. This suggests a possible source of the mucopurulent discharge which was found on clinical examination.

Twelve cases, or 15 per cent of the group, were complicated by otitis media. It will be seen from table 10 that there was no involvement of the ear without involvement of the sinus, and in every case but one, the involvement was on the same side as the otitic lesion. In this exception, both ears were involved, but

TABLE 10—Twelve Cases Studied for Complications of the Ears and for the Condition of the Sinuses

Involvement of the Ears	(Otitis Media)	X-Ray Film of Sinuses	Results of Clinical Examination
Both ears	(Second opened 3 days later)	Left maxillary	Negative
Both ears		Both maxillaries both ethmoids	Positive
Right ear	Two	Both maxillaries	Positive
Right ear		Right maxillary and ethmoid	Positive
Right ear		Both maxillaries left ethmoid	Positive
Left ear	Three	Both maxillaries both ethmoids	Positive
Left ear	Two	Both maxillaries	Positive
Left ear		Pansinusitis	Negative

the second ear was opened three days after the x-ray film was taken. As a second film was not taken, we do not know the condition of the sinus at the time of involvement of the second ear.

Only two of the cases of otitis media were clinically negative for evidence of sinusitis. In both instances the tonsils and adenoids were present. Two of the twelve patients had had their tonsils and adenoids removed.

None of the twelve cases required mastoidectomy. This fact precludes a discussion of that condition so far as this study is concerned.

For the purpose of further comparison, the series was divided into tonsillectomized and nontonsillectomized cases. As would be expected, the latter predominated. There were sixty-two of these, while eighteen patients had had their tonsils and adenoids removed. Aside from the evident increased incidence of scarlet fever and the greater involvement of the ear, the presence of this lymphoid tissue seemed to have little effect on the findings in this investigation. There were proportionately fewer mild cases in the tonsillectomized group than in the group with tonsils. It is true that the severe cases in the group with tonsils outnumbered those in the other group five to one, but as the difference between the two groups is more than three to one (in a small series such as this), this fact is not outstanding. It is interesting to note that the incidence of sinus involvement was not less in the tonsillectomized group, it was, in fact, proportionately greater.

COMMENT

It is realized that no acknowledgment has been made of the factor which chronic sinusitis might prove to have been in the formation of the various shadows seen in the two groups of cases. That it might be a factor is not denied, yet it is doubtful whether such an incidence as is brought out in this study could be found in any series. This report would be more complete and the conclusions more certain if a comparative series of x-ray films of normal persons of the same age groups and with the same seasonal variations could be included. It is our purpose to do this at a later period. In fact, the findings of this study suggest the value of a similar investigation in cases of influenza, measles and other infections of the upper respiratory tract. The history of chronic sinusitis was obtained in a few instances, but the lack of real understanding of this condition, especially in children as reported by their parents, precluded any reliable information on which to base some estimate of the prevalence of chronic infection in these cases. In the end, however, it makes but little difference whether or not a chronic condition is present. What has attracted our attention is the amount of sinus involvement in cases of scarlet fever and its possible significance.

A practical application of these findings is in the matter of contact cases. If there is a rather high percentage of sinusitis at the end of the usual period of isolation, a real responsibility rests on those who are entrusted with the final discharge of the patients. The responsible party, if not an otolaryngologist, should be well trained in the examination of the nose and throat. The question naturally arises, What significance should be placed on a sinus with thickened membrane at the time of discharge? Are all such sinuses sources of contamination, or does the thickening of the membrane represent only a residual reaction to the past infection something that will subside in a few more days? It is difficult to answer these questions with certainty, for it seems that one cannot condemn all patients any more than one can exclude every one. If they were all possible sources of infection, then the incidence of contact cases would be enormously high. Yet, because we have seen several patients who were probably infected from released patients of this series, whose sinuses showed thickened membrane, we believe that the patients can not be released without careful scrutiny. The value of a so-called discharge x-ray film is herewith suggested. While the finding of evidence of sinusitis in all cases of otitis media is interesting, it does not seem to possess

any practical value save perhaps in the field of prevention. Any patient with known sinusitis should be properly cared for and should receive such instruction as may be deemed advisable. This raises the question as to the methods of treatment employed in these cases. There was little done aside from ordinary cleansing. None of the group of eighty patients required special sinus treatment. As little as possible was done in the acute stages, and it was found that little needed to be done in the later periods.

SUMMARY AND CONCLUSIONS

1 Two series of cases of scarlet fever were studied, the first chiefly by roentgen examination, in the second, an attempt was made to correlate the clinical and roentgenologic findings.

2 In both series, roentgen evidence of sinusitis was present in approximately 90 per cent of the cases.

3 The clinical examination failed to support this evidence in every case.

4 There were 33 cases of otitis media among 292 patients in the first group, and 12 in the second series of 80 patients. In all of these there was roentgen evidence of sinusitis, and in all but 1 there was involvement on the side of the infected ear.

5 Without desiring to draw unwarranted conclusions in the absence of control studies, the question is raised as to whether or not sinus involvement is the rule rather than a complication.

ABSTRACT OF DISCUSSION

DR IRVING I MUSKAT, Chicago. In 1929, Fowler reported 100 cases of diseases of the ear in children with involvement of the sinuses in 80 per cent. In 1932, Campbell observed coexisting acute purulent sinusitis in many hundreds of cases of acute purulent otitis media in infants and children. Since purulent otitis media has always been known to be a frequent complication in scarlet fever, it was logical to stress the relationship between sinus disease and acute purulent otitis media in this disease. Silverman in July, 1932 published similar observations. In 292 patients with scarlet fever 91 per cent showed hazy to opaque sinuses and all thirty-three patients with otitis showed abnormal sinus shadows while no patients with clear sinuses had any aural complications. The frequent association of sinus disease with suppurative otitis media in children and infants is due to various causes. First any secretion in the nasopharynx is forced up into the middle meatus and sphenoethmoidal recess by the act of crying, sneezing, coughing, regurgitation or vomiting. The middle ear and the nasal sinuses are more vulnerable to infection in the young, because of the wide eustachian tube and the relatively wider sinus openings. The same relationship exists in the common head cold. I believe it is difficult to state which precedes the other. It may appear reasonable that with the severe nasopharyngitis in scarlet fever the eustachian tube and middle ear become infected before the nasal chambers do while in the common frequent rhinitis the ear is secondarily infected. There is also a marked seasonal variation in the occurrence of scarlet fever and its complications. The greatest incidence seems to occur from the middle of January to the middle of May. The concurrence of another exanthem, especially measles with scarlet fever also increases the incidence of aural and nasal sinus complications. The incidence of these complications decreases with increase of age. Observers differ as to the time of the occurrence of the otitis. Usually it manifests itself after the first five days of the disease. The data of Williams and Borden support the belief that aural complications of any degree of severity may arise at any time from the first day of the acute symptoms to the last day of convalescence. Early daily applications of mild silver protein or some other good antiseptic in the nose and throat tend to decrease the incidence and virulence of these complications. The streptococcal infection in scarlet fever is of a virulent type and such prophylaxis will probably be of no avail in averting

these complications in all cases. Suction of the nose in suppurative sinus disease, after shrinkage and early paracentesis of the infected ear should tend to lessen the course and severity of these complications.

DR HORACE R LYONS, Chicago. The authors presented a comprehensive study of a series of cases of scarlet fever. In the first series of 292 cases, 91 per cent showed one or more sinuses with positive roentgen signs. The antrums were most often involved. 113 per cent had acute otitis media and each of these patients had positive x-ray signs of a sinus infection on the same side, less than 2 per cent of the severe cases gave negative roentgen evidence of sinus involvement. The second series of eighty cases revealed that 91 per cent presented positive x-ray evidence of infected sinuses, 15 per cent of the patients had acute otitis media, all of whom likewise showed positive sign of sinus infection, and all but one had positive definite roentgen evidence of involvement on the same side. There were no instances of mastoiditis requiring surgical intervention. The real point revolves about the interpretation placed on the conditions observed. I do not believe that 91 per cent of scarlet fever patients have acute purulent sinusitis, yet I do not doubt that 91 per cent in this series presented positive roentgen signs of an infected sinus. Further, I do not believe that all cases of acute otitis media complicating scarlet fever presented acute sinusitis, yet I do not doubt that positive x-ray evidence was obtained in each. I prefer to believe that most of the x-ray evidence of sinusitis is due to the profound toxemia of scarlet fever and not to a true bacterial sinusitis.

DR O JASON DIXON, Kansas City, Mo. The authors have brought out an important point not to rely on the roentgen observations in the nasal accessory sinuses as a positive indication for surgical intervention. This is true also of roentgen observations in the sinuses in other diseases than scarlet fever. I was at one time enthusiastic over the radical treatment of the sinuses in scarlet fever, but I have decided to let them alone, because most patients get along better if not disturbed. In scarlet fever the sinuses become as much a part of the disease as the rash. Disease of the bone always develops more slowly than disease of the soft tissues, and there is no indication for radical intervention at the height of the acute infection. When surgical intervention is necessary, I do a two stage operation, the same as in mastoiditis with postauricular abscess. Under local anesthesia I drain the soft tissue abscess and leave the bone alone until the infection has subsided and the patient is over the acute attack. Scarlet fever patients do not do well under ether anesthesia, they are prone to serious complications such as nephritis or pneumonia. Local treatment does but little good. Since local treatment is done more to satisfy the patient and relatives than to cure the disease the ideal medication is mercurochrome or anything that makes a mousy stain. Cocaine, ephedrine or epinephrine should not be used. Orbital cellulitis, owing to leakage from an adjacent sinus, may simulate cavernous sinus thrombosis or meningitis. Positive roentgen observations at this time should not prompt one to undertake any emergency surgical measures that necessitate extreme trauma to acutely inflamed soft tissue. Such misdirected efforts may be the cause of actual and serious intracranial complications that were only apparently present. The virulence of the organism and the point of attack vary with different years. I rarely lose a case of scarlet fever. I think it is a much overrated disease. I do not think the serum therapy has anything to do with it.

DR EDWARD D KING, Cincinnati. Carmody in a report of sinus infection in children has found x-ray evidence of disease in very early cases. He states that x-ray evidence of sinus infection will not be found when the infection is confined to the surface of the mucosa. With the severe infection that accompanies scarlet fever the deeper structures will be involved and hence x-ray evidence of the infection will be present in almost every case. We've studied the sinuses of 100 children referred for tonsil and adenoid operations and found that from the roentgen ray and clinical aspects 16 per cent were diseased. Dixon has examined 500 consecutive medical cases and found 27 per cent giving positive x-ray signs of sinus infection. The author directed attention to the fallacy of concluding that x-ray evidence of sinus disease is sufficient. It must be proved clinically. Hubbard in 1912 called attention to the frequency of

sinus infection in scarlet fever. He felt that every scarlet fever case was potentially a sinus infection. Most authors have expressed the belief that sinus infection is a common complication of scarlet fever. Baumler, a German author, has come to the conclusion that sinusitis is the cause of from 20 to 40 per cent of the complications. The problem facing those in charge of the dismissal of these patients from quarantine is a serious one. It is conceded that from 2 to 10 per cent of patients discharged from quarantine will account for return cases. There is no way of distinguishing the scarlet fever streptococcus from other streptococci and hence cultures are not of great value. The period of infectivity is so much longer in scarlet fever than it is in any other contagion that one never knows when the patient is free from danger of transmitting the disease. It is my opinion that the sinus infection plays a major role in the prolongation of the infective period.

DR. GORDON D. HOOPER, Syracuse, N. Y. A point emphasized by several who have taken part in the discussion is that, while 90 per cent of these cases show x-ray evidence of sinusitis this does not connote a purulent condition in each case. On the other hand, four cases in the thickened membrane group in the second series were apparently responsible for a similar number of contact cases. This places a significance on the finding of thickened membrane by x-rays which cannot be denied. I feel that this necessitates more care in the discharge procedure in these cases.

GENERALIZED EDEMA OCCURRING ONLY AT THE MENSTRUAL PERIOD

WILLIAM A. THOMAS, M.D.
CHICAGO

In enumerating the factors concerned in edema, one has come to recognize (though not always to explain) a number of conditions most commonly associated with the phenomenon, such as alterations in chemical and mineral balance, metabolic disturbances within the tissues, changes in colloidal state of dispersion, quantitative and qualitative changes in serum proteins, or endocrine dysfunction, and is able at times to deal empirically with the conditions and to obtain satisfactory results.

Occasionally, however, one encounters situations entirely unique in so far as these recognized factors are concerned. It is the purpose of this paper to present two cases of generalized massive edema occurring only at the menstrual periods. As originally presented, the theme of the paper was edema, but the neurologic and gynecologic phases so overwhelmed the picture, and the internists had so little to contribute, that its appearance in this section is not unnatural.

The first case has been under careful and critical observation since 1926. When I described the condition last spring, a somewhat similar case was referred to me by an associate in the department of gynecology, and it is this case, less complete, that I shall describe first.

REPORT OF CASES

CASE A.—The patient was seen in April 1933, at the age of 29, with a baby 2 months old. Labor had been induced at seven months because of high blood pressure and albuminuria. The blood pressure formerly had been low.

For two years preceding this pregnancy, at each menstrual period and during the one period since, she had gained from 10 to 12 pounds (4.5 to 5.4 Kg.). She had a decreased urinary output, a severe bitemporal headache, blurred vision, vomiting and unusual behavior with swelling of the face, body and feet. Following this there was profuse polyuria (frequently 4 or 5 quarts in a day) with a rapid return to normal.

Her medical history is unusual. She weighed 100 pounds (45.3 Kg.) at marriage, gained 60 pounds (27.2 Kg.) in twelve months, lost 30 pounds (13.6 Kg.) on a diet and thyroid medication and weighed 145 pounds (65.7 Kg.) when last examined. Her basal metabolic rate was always found to be normal, but she never sweated as a child, and she felt worse following thyroid medication. Her periods were always irregular, varying from three to six months apart, and lasted only one day. She was given pituitary substance by hypodermic in Los Angeles for a year.

I observed her during only one cycle, the variation in weight shown on my office scales being 8 pounds (3.6 Kg.), the day following the onset of her diuresis. Owing to her financial difficulties (inability to procure a nurse) and the distance to the suburb in which she lived, I saw her only a few times before she moved to another city. A roentgenogram of the sella was normal in configuration, but the horizontal measurement was 9 cm., the very lower limit of normal.

The case first reported, however, is more satisfactory.

CASE B.—This patient is now 38 and has one child, aged 14. I have seen her in the office since 1922, and the present condition began in 1926. There is nothing significant in her family or past history except that a few months before, she accidentally cut both wrists in pushing a window closed, and was practically exsanguinated. Since then at each period she exhibited a typical picture, with edema, and a gain of weight reaching 11, 12 or even 14 pounds (5 to 6 Kg.). The edema was generalized, involving her face, body and legs. Vision was blurred at times almost absent. Examination of the eyegrounds showed marked choking of the disks. Headache was severe, referred to the interior of the skull and unrelieved by ordinary medication. The spinal fluid was clear, unaltered from normal and under markedly increased pressure. There was profound prostration, with nausea but no vomiting. Recovery in all these respects was rapid, a diuresis of 4,500 cc. in twenty-four hours was not unusual, and in the intervals she was well and active.

Observations carried on both at the time of the edema and in the intervals revealed no deviation from normal. There was no albumin in the urine except an occasional trace at the immediate onset of diuresis. The chemical observations on the blood were unaltered except for a general concentration of all constituents, often from 10 to 12 per cent. Functional tests of all types gave normal results.

The factors influencing this cycle unfavorably were: 1. Chilling. Regardless of other factors, if the patient became cold or chilled preceding the period the manifestations were aggravated. 2. Infection. The usual respiratory types always caused an increase in the edema. 3. Fatigue. If this occurred shortly before the menstrual period, the condition was aggravated.

For several years I labored to reduce the severity of the condition. With rest in bed and warmth for several days and liberal use of calcium (at first the lactate and later gluconate) the manifestations were not too severe, granted the absence of any aggravating factors. In 1931 she developed severe menorrhagia and progressive secondary anemia. In October, 1931, at operation, a chocolate cyst of one ovary and a degenerative process in the uterus were revealed. Hysterectomy and unilateral ovariectomy were performed. After convalescence, the identical clinical syndrome recurred. At this time there was enough current information to suggest roentgen examination of the sella turcica. Dr. Hollis E. Potter found a most unusual condition, which he had not encountered previously. The sella was normal in size and shape. At the base there was an oval area of translucency surrounded on all sides by a sharply demarcated zone which was semidense as compared to the clinoids—perhaps a calcification.

With this as a starting point, I gave the patient hypodermically a preparation of the anterior pituitary, with what appeared to me some success. However, newer preparations appeared and I tried a purified form of the anterior pituitary like sex hormone isolated from the urine of pregnant woman and the substance responsible for the Aschheim-Zondek test. The results were spectacular, for when this preparation was used, the edema was absent or present only in minor degree. The systemic evidences of menstruation recurred regularly. On the tenth, third and first days preceding the presumed period 1 cc. of this preparation was given for four months, with com-

plete absence of edema. Last summer I allowed three months to elapse with very little administration of the preparation mentioned. The first two periods were normal. The third resulted in a gain of 4 pounds (1.8 Kg) and moderately severe manifestations of edema. Resumption of the former dosage successfully controlled the subsequent two periods. Then a preparation she had carried with her during the summer, at this time three months past its expiration date allowed only minor swelling the first month, with quite severe symptoms the second month. Evidently there was some accumulative benefit from the previous two series of potent extract but none from the out-dated product. At present I am decreasing the dosage, with the hope of producing eventual independence, as I mistrust collateral results of excessive or prolonged administration of this substance.

COMMENT

Concerning the theoretical aspects of these observations, I do not feel at all secure, and prefer to present the results and clinical picture as I have observed them. However, the migraines of menstruation, as numerous discussions bring out, are in many respects similar. At first I felt that there was the action of a diuretic substance of the anterior lobe. This is quite opposed to the constant diuresis that occurs about three days following

Sella showing oval translucent area at the base surrounded by a semidense zone probably calcification

delivery, at the time this substance disappears from the urine. The antidiuretic principle of the posterior lobe is well known and used in diabetes insipidus. It has been suggested that this clinical picture is the antithesis of diabetes insipidus. More confusing still is the definite information, brought out recently, that this substance obtained from the urine of pregnant women is of placental, not pituitary, origin. Possibly it is another prohormone activating the anterior pituitary or opposing the antidiuretic activity of the posterior lobe. I feel, however, in respect to my original theme that however complex and interrelated these processes may be, the end-results—edema and diuresis—are functions of tissue thirst, depending on hydrophilic tissue states or the reverse, that is extrarenal factors rather than any alteration in renal function.

122 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR. GEORGE W. HALL, Chicago. As far as I know, there is nothing in the literature that corresponds in any way with the two cases that Dr. Thomas has just reported. The neurologic examination at the time I saw the patient presented nothing abnormal. Although Dr. Thomas has brought out that on occasions one of his patients had a definite papilledema

during these attacks, the interesting thing is that it occurred at the time of menstruation. The history of this case suggests that the condition may be related in some way, to certain types of migraine. The best monograph on migraine has been written by Riley of New York and has been followed by a paper by Riley and Brickner, in which thirteen cases of migraine were studied closely. Of the thirteen patients, eight were menstruating women, and seven had attacks of migraine only at the time of menstruation. Apparently there is some relationship between menstruation and the attacks of migraine. The authors were attempting to work out the relationship between the attacks of migraine and the presence of prolactin in the urine. Although they have come to no definite conclusions, they have shown the possibility of the relationship in these patients between the anterior pituitary secretion and the ovarian secretion. The internist is inclined to interpret this condition on some allergic basis, but it seems to me that there is a relationship between the endocrine secretions that has not been properly worked out.

DR. EDWARD ALLEN, Chicago. Not only is this report an important contribution to the problems of edema but it reemphasizes the importance of the cyclic changes of metabolism that occur in women with the menstrual function. Dr. Thomas does not offer an explanation why this substance when injected into his nonpregnant subjects should produce such a marked diuresis, while the pregnant individual continues to retain increasing amounts of fluid in her tissues at the same time that she is excreting excess quantities of the same material. Explanation of this discrepancy may reveal the underlying cause of all edema. Barnes of the University of Chicago found that injections of an anterior pituitary extract into normal dogs produces a marked diuresis. When the thyroid is removed, increased excretion of urine does not occur. The close relationship between the pituitary, the thyroid and the gonads is well established. Dr. Thomas has previously emphasized that the edema which occurs in nephritis is a disturbance of general cellular metabolism rather than a lesion of the excretory apparatus of the kidney. Zondek, Jeffcoate and others have recently reported increased amounts of prolactin A excreted in the urine of patients afflicted with fibromyomas and carcinoma, and especially in genital cancer. I have recently been able to produce changes in cell type of transplanted pelvic tissues in rabbits by the prolonged administration of glandular extracts. Under these circumstances tubal epithelium tends to assume the histologic characteristics of cervical mucous membrane. The secretory cells of the endometrium take on many of the cytologic trademarks of tubal epithelium, and in a few instances the follicular epithelium is distinctly abnormal. I have under observation now several rabbits with ovarian tubal and endometrial tissue transplanted into the anterior chamber of the eye, which have received daily injections of glandular extracts for a period of two months. There is marked evidence of cellular activity and growth in several of these transplants. Carefully controlled clinical experiments like the one Dr. Thomas has reported are of the utmost importance, but the indiscriminate use of the active glandular extracts should be stopped until more is known about them.

DR. WILLIAM A. THOMAS, Chicago. I have no further remarks, except that I think Dr. Allen is rather modest in reporting his work. There is a good deal of evidence from his laboratory, and from others, that there is a tremendous tissue stimulation as a result of the use of these substances and it does look as if there may be some approach to the understanding of uncontrolled growth of tissues, either benign or malignant, with the excessive presence of these substances either given artificially or formed in the body.

Fat in Blood of Diabetic Patients.—Fat is a far more insidious factor in the blood of a diabetic than is sugar. If the sugar in the blood increases it is reflected in the urine and makes itself known by polydipsia and polyuria. An increase in fat in the blood clinically may escape notice for weeks, months or even years.

Diabetic coma is the outstanding complication which is usually associated with increased fat in the blood for convenience recognized and estimated by us chiefly as cholesterol.—JOSEPH E. P. Fat and the Diabetic, *Am. England J. Med.* 209:519 (Sept. 14) 1933.

MANAGEMENT OF THE THIRD STAGE
OF LABORL A CALKINS, M.D., PH.D.
KANSAS CITY, MO

The proper management of the third stage of labor has received comparatively little real investigation either by research workers or by clinicians. Numerous studies of postpartum hemorrhage have been made, and considerable progress toward prevention and improved treatment has resulted. Almost without exception, however, various writers have failed to recognize that a large proportion of all obstetric patients offers the opportunity to prevent moderate hemorrhage. One textbook on obstetrics lists some twenty-five possible causes for postpartum hemorrhage and then goes on to say that a fairly large proportion of cases of hemorrhage does not fall into any one of these twenty-five categories. In other words, hemorrhages can and do occur in the absence of any one of the known causes. Moreover, a comparatively large loss of blood (not enough to be classified as "hemorrhage") is frequently passed by without much thought as to its etiology. There can be but one conclusion. The technic of management of the third stage of labor, as generally practiced, is deficient with respect to its control of blood loss. Litzenberg has taught that 90 per cent of postpartum hemorrhages are preventable, the inference being that the occurrence of postpartum hemorrhage is presumptive evidence of faulty management. My purpose in this paper is to show not only that 90 per cent of postpartum hemorrhages can be prevented but to show that 90 per cent of moderate losses of blood can be reduced to a minimum and that not over 10 per cent of all patients should lose in excess of 300 cc of blood in the third stage of labor. The importance of reducing blood loss and the consequent saving in mortality and morbidity is so evident that it requires no further emphasis.

Various estimates and (or) averages have been quoted in the literature covering the general experience of blood loss in various clinics. These figures are not entirely convincing because of the lack of description of the method of arriving at the amount of blood, and it remained for Williams¹ to point out the necessity of actually measuring the blood loss if one is to have any real idea as to the results. Williams' technic is as follows: "Immediately after the birth of the child, a sterile douche pan is placed under the buttocks of the patient, where it remains until all bleeding following the birth of the placenta has ceased. The entire amount is then poured into a graduate and actually measured in cubic centimeters and noted in the history." Litzenberg has further improved on this technic to the extent that he recognizes that not all the blood can be caught in a pan and that the linen, sponges and the like will naturally remove a considerable additional amount that cannot be measured in a graduate. This additional amount is estimated and added to the collected blood, and the whole amount, thus arrived at, recorded on the chart. One cannot emphasize too strongly the impor-

tance of both measuring and recording the amount of blood lost, for without this practice one regards the loss at only one-third to one-half the actual figures.

Williams¹ reported 1,000 consecutive spontaneous deliveries at full term with an average loss of 343 cc. of blood. He purposely eliminated the operative deliveries and premature deliveries and, by so doing, presented figures that do not represent a true cross section of all deliveries. Three thousand and two cases from Litzenberg's clinic, previously reviewed, demonstrated an average blood loss of 462 cc. This series included operative deliveries and premature deliveries as well as normal full term deliveries and, therefore, more nearly represents a true cross section of obstetric experience. This average figure also included the "estimated" in addition to the "measured" loss of Williams. It is quite in line with De Lee's estimate of 500 cc, Ahlfeld's 500 cc and Tarnier's 600 cc.

It is probably fair to assume that in most clinics some part of the 500 cc is due to the fact that most of the patients in such clinics are delivered by interns or younger residents. Physicians have quite generally assumed that their own figures would be more favorable because of their skill and experience. In 1,157 privately conducted labors and employing the Williams technic of blood measurement, Plass² had an average loss of 317 cc. This figure, however, is not directly comparable with Williams' average of 343 cc because Plass did not exclude from his series operative deliveries or premature deliveries. Whereas the difference between his average and that of Williams is only 26 cc, the actual saving is probably in the vicinity of 50 cc due directly to the skill of the attendant. Fifty cubic centimeters subtracted from the average blood loss of 450 or 500 cc is an appreciable but not a phenomenal saving. It would seem that some change in the management of the third stage would be necessary to effect a marked reduction in blood loss.

Williams' technic of management of the third stage as described in his textbook³ is as follows:

Just as soon as the child is born, the hand is laid upon the abdomen, and if the uterus be felt as a hard globular mass, it is left absolutely alone. On the other hand if it happens to be soft and flaccid it is gently kneaded until firm contractions are induced. The condition of the uterus is then carefully watched by applying the hand to it every few minutes, but kneading it only when necessary. In the majority of cases, after a lapse of ten or fifteen minutes it is noticed that the fundus rises spontaneously several centimeters above the position which it had just occupied, and at the same time remains firm and hard. This change indicates that the placenta has become separated from the uterine wall and is distending the lower uterine segment or upper portion of the vagina. The placenta is now expelled by grasping the uterus and making a downward pressure in the axis of the superior strait, using the uterus merely as a piston to shove the placenta through the vagina. Immediately following the birth of the placenta, the uterus should again be palpated; normally it will be found firmly contracted and retracted and (if it remains so) there is no danger of hemorrhage. But, on the other hand if it shows any tendency toward relaxation, it should be kneaded until it contracts, and the hand kept constantly upon it, so that beginning relaxation may be detected and combated. There is usually no danger of relaxation and hemorrhage, providing no signs of it appear during the first hour after the expulsion of

From the Department of Obstetrics and Gynecology of the University of Kansas School of Medicine.

³ Williams, J. W. *Obstetrics*, ed. 6. New York: D. Appleton & Co. 1930.

the placenta. Accordingly the condition of the uterus should be carefully watched during that period by the physician or nurse. While pituitary extract is not necessary, the prompt and vigorous contractions which it induces add somewhat to the peace of mind of the physician and can do no harm. On the other hand, the drug should not be employed so long as the placenta remains in situ for fear that it may give rise to an hour glass contraction of the uterus and thereby unnecessarily prolong the third stage of labor.

This technic may be regarded as more or less standard, as the slight differences recommended by De Lee and others are all of relatively small significance and,

Chart 1—Blood loss in the third stage of labor incidence of various serial amounts

from the figures quoted it seems fair to assume that this technic will produce an average loss of from 400 to 500 cc per patient with average skill of attendants.

At the suggestion of Dr. Litzenberg I modified this technic to the extent that the hand was placed on the uterus immediately after the birth of the baby and *kept there constantly*. The reason for this change is that, not infrequently the patient's uterus may relax very suddenly and very markedly and sometimes in the space of a few seconds. I believe that it is quite as important to keep the hand on the uterus before the delivery of the placenta as afterward, and there is general agreement on the latter point. By carrying out this suggestion I learned that placental separation takes place much earlier than I had formerly supposed. Immediately after the delivery of the baby the uterus contracts and assumes a flattened discoid shape, which is maintained for a relatively short time. The shape of the organ then becomes globular. This change in shape indicates placental separation. I believe that the placenta should now be gently expressed without waiting for the rising of the uterus in the abdomen as that does not take place until several minutes later. It seems fair to assume that in these several minutes in which one is waiting for the uterus to rise in the abdomen a considerable bleeding may take place into the uterine cavity. Nearly all authors recommend that the placenta be expressed as soon as it is definitely separated. At about the time the uterus changes in shape there is also a slight trickle of blood from the vagina. I believe that this indicates separation and while I do not regard it as certainly indicative of more than partial separation that it is confirmatory to the sign of change in shape.

Making use of this modification of Williams' technic I⁴ was able to report an average blood loss of 222 cc for 853 cases. This material reduction in the average blood loss quite substantiates Williams' con-

tention that the placenta should be expressed as soon as it is separated. It seems hardly necessary to reiterate that no attempt at expression of the organ should be made until it is completely separated from the uterine wall. This difference in technic from that recommended by Williams is merely an earlier recognition of separation.

Encouraged by this material saving I have attempted some other modifications of technic one of which seems to have been quite productive of improvement. Having determined that placental separation has taken place, one should not proceed at once to express the placenta but should first massage the uterus quite vigorously if necessary, to insure firm hard contraction and then, by squeezing and downward pressure, expel the organ. This modification materially minimizes the bleeding which otherwise frequently follows immediately on or really with the delivery of the placenta. Adding this slight modification to the technic, I am now able to report an average loss of 179 cc for the last 800 consecutive cases. Nearly all of these patients were delivered by the intern or the resident and yet the average blood loss was within a few cubic centimeters of that of the patients delivered by the staff men who use this technic.

It is important to emphasize the constant contraction of the uterus both before and after separation as well as during and after delivery of the placenta. Periodic relaxation does not seem necessary in the mechanism of separation, either to the promptness or to the completeness of separation.

Inspection of charts 1 and 2 indicates that this saving of blood loss is not merely an elimination of hemorrhages but it is, even more, a reduction of moderate losses (from 200 to 600 cc), as 71 per cent of my patients lost 200 cc or less and 89 per cent lost 300 cc or less. Williams states that a loss of blood exceeding 600 cc should be considered abnormal. I believe that

Chart 2—Blood loss in the third stage of labor showing (1) results of new technic of management and (2) necessity of individualizing management

a loss of blood exceeding 400 cc should be considered abnormal. Only 5 per cent of the patients lost more than 400 cc of blood and 2.5 per cent lost more than 600 cc. In Litzenberg's cases 216 patients in a thousand lost 600 cc or more thus by these changes in technic 88 per cent of moderate and large hemorrhages are prevented. Of Litzenberg's patients 221 in a thousand lost between 400 and 600 cc of blood as compared to 33 in the group reported here. A saving of 85 per cent of moderately large losses not ordinarily classified as hemorrhages. Furthermore analysis and

⁴ Calkins, J. A. Factors Governing Blood Loss in the Third Stage of Labor. *Am. J. Obst. & Gynec.* 18: 58 (April) 1929.

review of the events associated with the third stage of labor in each individual patient will usually reveal, even to an intern why the patient lost in excess of 300 cc of blood. My associates and I practice such a review for every loss in excess of 300 cc. Finally, I believe that, unless an obstetrician has as a goal in each individual case a blood loss of less than 100 cc, he cannot hope to render his patient the greatest service in this respect.

TECHNIC OF MANAGEMENT

The technic of the management of the third stage of labor might be stated as follows. Immediately after the delivery of the baby, the hand is placed on the abdomen, the uterus is held very gently with the fingers behind and the thumb in front and with no attempt to massage the organ unless it shows signs of relaxation and flaccidity. As soon as it changes from a discoid to a globular shape and a trickle of blood appears from the vagina, the organ is vigorously massaged until it becomes firmly contracted and then, by squeezing and gentle downward pressure, an attempt is made to express the placenta. Should the placenta not come out readily, no further attempt is made to express it and no further massage is instituted until some sign of enlargement or flaccidity appears or there is an increase in bleeding from the vagina. Immediately after the delivery of the placenta, the uterus is again massaged to obtain firm contraction, and the hand is kept constantly in contact with the uterus for a period of one hour or until such a time as the attendant assures himself that there will be no further tendency toward relaxation or flaccidity. One cubic centimeter of solution of pituitary is administered hypodermically immediately after the delivery of the placenta—never before. Whereas I believe that constant moderate (physiologic) contraction is necessary during the separation phase of the third stage, I am in accord with Williams that excessive (pathologic) contraction, as occasionally induced by solution of pituitary, is potentially productive of real pathologic changes. There is an obvious reason why solution of pituitary, given immediately after the delivery of the baby, does not often cause trouble. It requires from seven to twenty minutes to produce a severely hard contraction of the uterus and in the majority of instances the placenta will have been delivered before the expiration of that time.

Employment of this technic of management has resulted in an average duration of the third stage of labor of approximately four minutes; the majority of cases showing completion of delivery of the placenta in one two or three minutes. Although I do not believe that delayed separation of the placenta causes any increase in bleeding, I do believe that delay in expulsion of the organ after its separation does cause increased bleeding. I find that not more than one case in eight will be delayed for as long as ten minutes after the delivery of the baby and that in at least one case in five separation of the placenta is completed within thirty seconds after the delivery. Constant contraction of the uterus both before and after the delivery of the placenta seems to be of major importance in reducing blood loss to minimum figures.

CONCLUSION

Constant attention to constant uterine contraction means controlled blood loss.

406 West Thirty-Fourth Street

ABSTRACT OF DISCUSSION

DR JENNINGS C. LITZBERG, Minneapolis. As women necessarily lose blood after delivery physicians are apt to look on a considerable loss of blood as not particularly significant. If physicians measure the blood that is lost in their obstetric cases they will be surprised at the reduction of morbidity. Dr Calkins has shown that there has been a saving of large quantities of blood. I want to call attention to the author's summary, possibly the shortest on record in medical literature. "Constant attention to constant uterine contraction means controlled blood loss." Dr Calkins has not been presenting something to show that so many cubic centimeters of blood may be saved or to present a technic but to emphasize the idea that the loss of blood in women from childbirth must be reduced to an irreducible minimum.

DR F. J. SCHWARTZ, St. Cloud, Minn. What are the effects of hypnotics used during the first stage on the loss of blood during the third stage, especially of sodium amylal, and what is the treatment?

DR HENRY P. NEWMAN, San Diego, Calif. The former routine of attendance in childbirth consisted in the obstetrician's presence at the delivery and the subsequent oversight of the mother and child for the next ten days. But this is not obstetrics of today. Our responsibility should end only with the restoration of the mother to normal health. In view of the number of deaths from cancer, 100,000 or more yearly, is it not the duty of obstetricians to use every precaution possible? Even in this day of preventive medicine and health supervision it is still true that faulty obstetrics is responsible for many distressing, if not malignant, conditions in women. The frequent abrasions or tears in the puerperal cervix, entirely overlooked by the attendant in many instances, leaving a rough unhealed surface continuously irritated by the catarrhal discharge, constitutes a typical condition for the production of cancer. As a preventive measure I have to offer tracheloplasty, a name given by me to the surgical restoration of the cervix many years ago. This removes the abraded ulcerated surface and by the formation of an anterior and posterior flap, inverted and attached, restores the outlines and function of a normal cervix. What is more important, it lines the endocervical area with an epithelial membrane much more resistant to cancerous invasion.

DR E. L. CORNELL, Chicago. I was surprised that Dr Calkins did not mention the use of solution of pituitary in the third stage of labor. During the past fifteen years I have been able to control the amount of bleeding in the third stage of labor by the use of from 0.5 to 1 cc of solution of pituitary following—not before—the delivery of the baby. As soon as the baby is born, the solution of pituitary is given. I was surprised to see the marked difference in the loss of blood following its routine use. There is one objection to the use of solution of pituitary after the delivery of the child: occasionally an hour-glass contraction of the uterus occurs and the placenta is retained in the uterus. I believe it is bad teaching to massage the uterus in the third stage as a routine measure. A certain amount of damage to the uterine structure will be done which though not visible is similar to the damage done by the masseuse to the muscles of the extremities by too vigorous massage. It has not been my practice to control the action of the uterus during the third stage, because I have found that the use of solution of pituitary has caused almost immediate contraction and separation of the placenta. There are occasionally a few cases in which this does not hold true. I agree with the author that it is essential to control the amount of blood loss, and that the patients recover better, and leave the hospital in a much better condition.

DR LEROY A. CALKINS, Kansas City, Mo. I am unable to answer the question about amylal from personal experience. My stand on the use of solution of pituitary is given at length in the paper. I am sorry that Dr Cornell did not present figures on blood loss in substantiation of his faith in solution of pituitary. I cannot help but feel that opinions without actual figures to back them up mean little or nothing. I administer solution of pituitary immediately after the delivery of the placenta but never before. Whereas I believe that constant moderate physiologic contraction is necessary during the separation phase of the third stage, I am in accord with

Williams, who states that excessive or pathologic contraction, as occasionally induced by solution of pituitary is potentially productive of pathologic states. There is an obvious reason why solution of pituitary, given immediately after the delivery of the baby does not frequently cause trouble. It requires from seven to twenty minutes to produce a hard contraction of the uterus by this means, and in the majority of instances the placenta will have been delivered before the expiration of that time. It seems unnecessary to give solution of pituitary immediately after delivery of the baby when 700 out of 1000 patients are delivered with less than 200 cc of blood loss and only some 2 per cent develop hemorrhage. I hope that Dr. Cornell will substantiate his routine by presenting his figures on loss of blood.

LEAD POISONING IN CHILDREN

CHARLES F. McKHAHN, M.D.

AND

EDWARD C. VOGT, M.D.

BOSTON

The continued occurrence of lead poisoning in children, despite the efforts of physicians, health agencies and insurance companies to disseminate information concerning this preventable disease, warrants the presentation of a review of certain phases of the condition and a further report of the cases observed in this clinic.

SOURCES OF LEAD

Lead poisoning in infants may follow the prolonged use of lead nipple shields,¹ in Japan poisoning has occurred frequently from the use by the mother of face powder containing lead. In infants and older children the ingestion, over a period of time of water containing even small amounts of lead may result in intoxication. Recently there was reported an extensive series of cases of lead poisoning following the inhalation of fumes in homes where storage battery casings were used as fuel.² However, most frequently the ingestion of lead is a result of the habit observed in small children of eating unusual substances.³

Perversions of appetite designated pica leading to the ingestion of foreign substances such as sand, coal, cloth, hair or paint are observed in mentally defective and neurotic children in those suffering from anemia and in those harboring intestinal parasites. In the majority of cases of lead poisoning due to ingestion of paint, the pica has apparently been merely a pernicious habit unrelated to any underlying abnormal condition. The incidence of lead poisoning (table 1) is highest in infants and small children in whom teeth are erupting and in whom there is a great tendency to put things into the mouth.

The lead industry and the manufacturers of cribs and toys, informed of the danger to small children from the ingestion of lead paint have cooperated by substituting other types of pigments for the lead pigments formerly used. New cribs are seldom painted with lead paint, and the better grades of toys are largely free from lead pigment. Painted woodwork and painted furniture continue to present sources of lead available to the child.

Intoxication following the ingestion or inhalation of lead appears to be dependent on a number of factors. Of primary importance are the amount of lead ingested and the period of time over which it is taken in. The absorption of small amounts of lead by all persons, whether in urban or in rural populations, seems to be of normal occurrence and is said to be unaccompanied by danger.⁴ An increase in the amount of lead ingested, or the continuation of absorption over a period of time, may lead to intoxication. Age is a third factor of importance. Children appear more susceptible to severe intoxication than adults. A similar observation is made in experimental animals for likewise the young animals seem more susceptible to lead poisoning than do the adults of the same species. In addition to the influence of age on susceptibility to lead, there is observed considerable individual variation in tolerance to the metal. Some children, after the ingestion of moderate amounts of the metal, rapidly develop encephalitis. Others are capable of tolerating quite large amounts with the minimal development of symptoms but with however the deposition of abnormal amounts of lead in the body, a condition which we designate latent lead

poisoning for under certain circumstances such patients may mobilize the lead deposited in apparently inert form and thereafter develop serious manifestations.

SYMPTOMS

Usually the ingestion of lead in small amounts has taken place over a period of weeks or months before symptoms are noted. The early manifestations are traceable to disturbed function of the gastro-intestinal tract. Anorexia, constipation, vomiting and abdominal cramps are commonly observed associated with a variable degree of anemia. More serious symptoms are those referable to the central nervous system. Peripheral neuritis, the usual accompaniment of lead intoxication in adults is observed infrequently in children, particularly in the younger age groups where the development of encephalitis is more common.

Evidences of the onset of encephalitis are a change in the mental state of the child and more persistent vomiting, frequently of projectile character. Visual disturbances, alteration in rates of pulse and respiration, delirium, stupor, coma or convulsions may ensue. These manifestations often are accompanied by an elevation of the blood pressure, choking of the optic disks and, in extreme cases separation of the cranial sutures. When death occurs it follows a period of

coma or convulsions and appears to be due to central respiratory failure, as the heart continues to beat for some time after respirations cease.

Although localized lesions such as minute hemorrhages and cellular infiltrations have been found in the brains of patients who have succumbed to lead encephalitis,⁸ it is possible to attribute the train of symptoms observed in the disease to the rapid development of generalized increased intracranial tension due to intense cerebral edema.

Cerebral edema in a child with lead poisoning presenting cerebral symptoms was observed by Chvostek in 1897. A young girl with lead poisoning developed headache, vomiting, a slow pulse rate, coma, choked disks and vasomotor disturbances. At necropsy the meninges were clear. The whole brain appeared swollen, the convolutions were flattened, the medulla was pressed into the foramen magnum, and the ventricles were very small. This description of the gross appearance of the brain in children succumbing to lead encephalitis has been confirmed repeatedly.

Weller⁹ studied the pathology of lead encephalitis in experimental animals and observed a similar intense cerebral edema. We also have produced lead encephalitis in animals and in the course of our experiments have confirmed Weller's observations.

If a child survives severe lead encephalitis there frequently remain sequelae indicating cerebral injury of a permanent nature. Cerebral atrophy or degeneration may become manifest in cerebral palsy, epileptiform seizures or mental deficiency. By encephalography the extensive nature of the injury may be demonstrated. Although lead is known to be deposited in the brain and may directly injure or kill the nerve cells, the destruction of brain tissue which is observed need not be explained by a specific action of the metal but may be attributed to degenerative processes resulting from

impaired circulation to the brain during the prolonged state of intense cerebral edema.

While an encephalopathy is the usual form of lead poisoning seen in infants and children, milder types of intoxication are encountered which, although not dangerous to life, are of great importance in that their recognition may result in the prevention of the more serious and frequently fatal encephalitis. Neuritis has been mentioned. Gastro-intestinal disturbances are present in almost all cases. In addition to those symptoms and signs which have been mentioned, the ingestion suddenly of large amounts of lead may, by local irritation, induce bleeding into the lower intestinal tract with the passage of fresh or changed blood in the stools. Occasionally also the kidneys are irritated so that a transient albuminuria or hematuria is observed. Glycosuria was seen frequently in our more severe cases, especially those with encephalitis. There was considerable doubt as to whether the elevated blood sugar level and glycosuria were due to injury to the pancreas or whether they were of the type designated as cerebral and observed in other forms of encephalitis.

The incidence of lead encephalitis in the series of cases of lead poisoning observed since 1924 in this clinic is shown in table 2. The relatively high fatality rate and the frequency of permanent sequelae are to be noted.

DIAGNOSIS

Lead encephalitis must be distinguished from other types of disease with cerebral involvement, notably various forms of encephalitis and meningitis. The history of ingestion of lead and the presence of symptoms of gastro-intestinal disturbance preceding the development of cerebral manifestations suggest lead poisoning. In our opinion the cerebral manifestations are evidences only of the cerebral edema and are not pathognomonic of lead intoxication. Nor are the changes in the cerebrospinal fluid of diagnostic importance in distinguishing lead intoxication from other forms of

TABLE 3—Determinations of Lead and Calcium in the Cortex of the Shaft of the Femur and in the Lead Line at the Growing End of the Femur*

	Calcium Mg. per Gm. of Bone	Lead Mg. per Gm. of Bone	Lead Mg. Calcium Gm.
Cortex of shaft	909.0	0.114	0.546
Lead line	83.5	0.602	7.210

* By chemical examination the lead line was found in this case to contain over five times as much lead per gram of bone as did the cortex of the shaft, while the lead/calcium ratio (column 3) was thirteen times as great in the lead line as in the shaft. Chemical examinations were made through the courtesy of Dr. L. T. Fairhall.

encephalitis. In cases of lead encephalitis the spinal fluid escapes under increased pressure, oftentimes as high as from 600 to 700 mm. of water pressure. The fluid is clear and colorless, contains usually a trace of globulin and shows an elevation of the total protein. Occasionally a slight pleocytosis is observed.

Examination of the blood for basophilic stippling of the red cells is of diagnostic aid. Stippling of the red blood cells is not, however, peculiar to lead poisoning, nor is it found even with constancy in cases of the disease. Particularly it is likely to be absent in cases of so-called latent lead poisoning, and it may be absent even in children showing definite symptoms of intoxication. In patients and experimental animals the numbers of stippled cells in the circulating blood vary from

day to day and reflect perhaps more accurately the level of transport of lead in the blood than the total amount in the body or the amount deposited in certain organs and producing symptoms referable to these organs

The lead line observed in the gums of adults suffering from lead intoxication is found rarely in children. Only a few of our patients had a lead line in the margins of the gums. When present the lead line is a valuable sign, although it must be distinguished from similar lines produced by other heavy metals, notably silver.

Among the most useful aids in the diagnosis of plumbism in children are the recently recognized changes in the bones demonstrable by roentgenogram. These changes, recognized independently by Park,¹⁰ Caffey¹¹ and one of us (E. C. V.)¹² in this country and by various foreign investigators,¹³ consist of zones of increased density at the growing ends of the long bones and at the margins of the flat bones. The development of these changes appears to be dependent on the increased deposition of lead in place of calcium in the growing ends of the long bones as well as on a definite abnormality in the microscopic structure of the bone formation. The results of chemical analysis of the bone substance of the dense band as compared with that of similar material taken from the shaft are shown in table 3 and indicate that there is a definite increase in lead in the dense bands observed at the metaphyseal margins of the long bones. Microscopic examination shows further that in cases of plumbism the trabeculae in these rapidly growing parts of the bones are more numerous and are more closely packed together than in normal bone.

This change in the bones has proved to be one of the most constant observations in lead poisoning in children, and has led to the discovery of numerous cases with minimal symptoms or with unusual clinical manifestations. Rarely has the lead line in the bones been absent. In one patient, 20 months of age, a diagnosis of lead encephalitis was made and confirmed by chemical analysis of the excreta for lead, but the diagnostic lead line in the bones was absent. The child improved gradually and within a few weeks had developed the definite dense band found in lead poisoning. Heavy lines in the ends of the long bones are not peculiar to lead poisoning, as the ingestion of phosphorus and other substances may produce similar lines.¹⁴ Narrow lines of sufficient density to be confused with a lead line may be found at the ends of the long bones in healing rickets and in infants with vitamin A deficiency. Occasionally in the normally growing child there may be a zone of increased density at the metaphyseal margins of the long bones, owing only to a heavy deposit of calcium. These lines should not be confused with the lines observed in lead poisoning, which are of greater density and width (fig. 1).

Further confirmation of the presence of lead in the cerebrospinal fluid or blood may be obtained by spec-

troscopic examination.¹⁵ This determination is said to permit an exact diagnosis of the presence of lead within twenty-four hours after blood is withdrawn from the vein of the patient.

The demonstration of lead in the excreta of children by chemical examination is not adequate evidence of intoxication as it has been shown by Kehoe⁶ and confirmed in this clinic that normal children excrete small amounts of lead in the urine and stools. However, patients with lead poisoning excrete much larger amounts of the metal than do normal children, so that quantitative determinations of lead in the excreta properly appraised, may be accepted as satisfactory evidence of plumbism.

TREATMENT

Although it is impossible within the scope of this paper to discuss the chemistry of lead in the body, a brief statement may aid in the understanding of the suggested methods of treatment.

Aub and his co-workers¹⁶ have pointed out that lead in the body is absorbed, transported, deposited and excreted much as is calcium, so that, in general, factors

Fig. 1—A dense transverse bands at the growing ends of the long bones observed in a child with lead poisoning. B roentgenogram of the long bones of the same patient four months later. Note the greater breadth of the bands.

which influence calcium metabolism might be expected to have an influence on lead. Lead is absorbed through the lungs or intestinal tract and, in rare instances, through the skin. It is carried in the blood stream presumably as the phosphate and is deposited in various organs, especially the brain, liver, pancreas and bones. Lead deposited in the organs of the body may induce the symptoms referable to the various systems, but lead deposited in the bones is in an inert form. Thus in relieving lead poisoning measures are usually recommended which tend to hasten the removal of lead from the circulation and the deposition of the metal in the bones. To this end calcium salts¹⁶ or phosphates¹⁷ are administered to diminish the solubility of lead in the blood and vitamin D is given to hasten the growth

of bone. The efficacy of these therapeutic measures is difficult to evaluate, as the milder cases of intoxication show prompt improvement if the ingestion of lead is prohibited and if the child remains free from infection and in a good state of nutrition.

Removal of lead from the body, or deleading, may be accomplished by inducing an acidosis or an alkalosis, by deprivation of calcium or by the administration of parathyroid extract-Collip¹⁸. In view of the fact that acute infection or the development of acidosis may induce symptoms in a child who harbors lead in the bones but who has been symptom-free for a period of time, and furthermore because efforts at deleading have resulted in the recurrence of cerebral symptoms, we have given up the attempt to delead our patients.

Fig 2—A roentgenogram of the skull of R. M. on her admission to the hospital. No abnormality is noted. B roentgenogram of the skull three weeks after admission showing the sutures widely separated. C encephalogram seven weeks after the onset and three weeks after the subsidence of symptoms of lead encephalitis. Cerebral atrophy is evidenced in the markedly enlarged ventricles and the excess of air over the cortex of the brain.

Although danger of return of the symptoms of lead poisoning persists for some time, it gradually subsides owing to the spontaneous elimination of the metal.

The treatment of children who have already developed lead encephalitis is not satisfactory. Lead deposited in the brain appears to induce intense cerebral edema which is highly resistant to the ordinary methods of combating cerebral edema. Intravenous injections of magnesium sulphate or of hypertonic solutions of salt or dextrose have had only temporary

effects. It would appear that life can be prolonged or maintained by the use of drugs which control the convulsive seizures, but the unfortunate sequelae cannot be prevented by these substances. In the more severe cases separation of the sutures of the skull has occurred, resulting in relief to the patient through spontaneous cerebral decompression. The pressure required to accomplish this decompression is great and may account for the permanent cerebral injury that is so common among the children who survive the acute encephalitic stage. The following case illustrates the course of severe but nonfatal lead encephalitis.

REPORT OF A CASE

R. M., a girl, aged 2½ years, was admitted to the hospital because of anorexia, drowsiness and tremors of three days duration. For three months she had vomited, suffered from abdominal cramps and been constipated. The history revealed that for four and a half months she had been chewing paint from the woodwork and furniture of the house. After admission to the hospital she remained in a stuporous state, refused food, continued to vomit almost everything taken and constant tremors of the extremities and periodically suffered from generalized convulsions.

Examination of the blood showed a moderately severe anemia, with numerous stippled cells present in the smears. Roentgenograms of the long bones showed definite lead lines. The blood pressure was elevated. Severe papilledema developed rapidly, and over a period of three weeks the sutures of the skull gradually separated (fig 2 A and B). The spinal fluid was found to be under greatly increased pressure, globulin was present, the sugar content was normal and the cell count was elevated, ranging in various examinations from 19 to 31 mononuclear cells. Therapy directed toward hastening the deposition of lead in the bones as well as measures designed to relieve increased intracranial tension were apparently without effect on the course of the disease. An operative procedure, in the nature of a widespread flap decompression, was contemplated but was not performed. Following the spontaneous decompression whether or not because of it we cannot say, she began gradually to improve. The tremors subsided and the vomiting ceased. As she became less stuporous it was apparent that she had become mentally defective and that she was almost totally blind. With the disappearance of papilledema the optic disks became very pale. Encephalograms made seven weeks after admission and three weeks after the subsidence of symptoms of increased intracranial pressure showed considerable cerebral atrophy as evidenced by markedly enlarged lateral ventricles and an excess of air over the cortex (fig 2 C). Further observation of the child over a period of several months indicated that her mental condition gradually improved and fortunately her vision returned at least in part, but she remained obviously and probably permanently retarded mentally.

In view of the failure of therapy in children with cerebral manifestations of lead poisoning, we have been prompted to undertake the experimental investigation of lead encephalitis. By means of organic lead salts given by mouth it was found to be possible to induce with great regularity a fatal type of lead encephalitis in rats, guinea-pigs and rabbits. After a few days the animals developed tremors which were followed by generalized clonic convulsions. After a variable period of convulsions death ensued from respiratory failure. Measurements of the blood pressure of guinea-pigs in the stage of tremors or convulsions of lead encephalitis showed an elevation almost 50 per cent above the normal level established by similar determinations in control animals of the same ages and weights. The brains of animals succumbing to lead encephalitis showed the intense edema described by Weller.

Thus lead encephalitis induced experimentally in guinea-pigs resembled in many aspects the disease as

¹⁸ Aub J. C. and Hunter D. Lead Studies. XV The Effect of the Parathyroid Hormone on the Excretion of Lead and of Calcium in Patients Suffering from Lead Poisoning, *Quart. J. Med.* 20 123, 1927.

observed in infants and children. After producing and studying the manifestations of lead encephalitis in upward of twenty guinea-pigs we undertook to test the efficacy of various therapeutic agents. Thus far in a series of over fifty animals we have been unable to influence the course of the disease if treatment has been delayed until the animal is in a state of convulsions. Control of the convulsive seizures has been accomplished by the use of magnesium sulphate, phenobarbital, pentobarbital-sodium, amytal or paraldehyde, with considerable prolongation of life but without effect on the final outcome. The parenteral administration of calcium salts, sodium salts including phosphates, iodide, thiosulphate, ferricyanide and thiocyanate, and other drugs which theoretically might have some effect on the solubility of lead in the blood or the deposition of the metal in the body, has been tried without influence on the course of the disease. Other means of combating lead encephalitis in experimental animals are now under investigation.

SUMMARY

A diagnosis of plumbism can be made in children in the early stages of intoxication by the correlation of the history, physical signs and laboratory data in conjunction with the roentgenologic findings. Cerebral manifestations seldom occur in patients who receive, at this stage of the disease, treatment directed toward hastening the deposition of lead in the bones. Although progress has been made and is being made in the understanding of lead encephalitis, the treatment of patients with lead encephalitis remains in an unsatisfactory state.

The attack on lead poisoning in children must be made largely through prophylactic measures. Realization by physicians of the dangers to children of the continued ingestion of lead and the dissemination to mothers of information on the subject should result in prevention of the disease.

ABSTRACT OF DISCUSSION

DR R. A. KEROE, Cincinnati. I shall emphasize a few points made by the authors and speak briefly on lead excretion. Although lead encephalitis occurs in adults, it is relatively rare, occurring only when massive doses of lead have been absorbed. In children, on the other hand, it is not infrequent. It is of particular interest and importance that in children with lead poisoning there is a striking tendency for symptoms of the central nervous system to develop indicating the fundamental difference in the disease in children and adults. Encephalitis in children as in adults, has a bad prognosis. From available figures one concludes that the prognosis in children and the outlook for complete recovery are even somewhat worse than in adults. The preventive aspect of this problem should therefore be greatly stressed. Since the authors' figures have shown that this condition occurs at the period when children are most likely to eat abnormal things and to chew various objects in their environment, pediatricians should be alert to note abnormal appetite and behavior. Pica being the most frequent cause of lead poisoning in children, strenuous efforts must be devoted to eliminating lead from their environment. This situation is very serious in Queensland. A large number of cases have been reported presumably because children play on weathered, lead painted verandas where the lead pigments have dusted out to the surface. The contributions of the roentgenologist to the diagnosis of lead poisoning are among the most significant in our day, and it is an unfortunate limitation that they are applicable only to children. This sign of the line in the bones is extremely important. Recognizing however that it may not always be possible to differentiate this line from certain other densities that occur on the epiphyseal end, it is of some consequence to stress the diagnostic importance of lead in the excreta.

It has been shown beyond any reasonable doubt that lead occurs normally in the excreta of children as of adults. The quantity of lead that may be found under normal conditions is small. The levels of lead in the excreta that can be demonstrated to have clinical significance are comparatively well defined. It is thus possible with accurate analytic methods to recognize the probable existence not only of lead poisoning but also of lead exposure in unusual amounts, both in children and in adults. This method as an adjunct to the much quicker and much more convenient x-ray method, will aid materially the correct diagnosis of lead poisoning in children.

DR ROBERT A. STRONG, New Orleans. In 1914 I reported a case of lead encephalitis in a child 18 months old and at the time I could find only six other reports in young children although the literature at the time seemed to indicate that it prevailed extensively among adult workers in the lead industry in France. As the authors have stated, physicians must be lead conscious in order to be able to elicit lead poisoning. A considerable amount of lead poisoning has been overlooked in these little patients. Since hearing papers such as Drs McKhann and Vogt have presented I have been more alert. I have seen three cases in New Orleans during the past winter in which the lead line was demonstrable. Unfortunately, the cases had advanced until the central nervous system was involved and consequently the cases were not amenable to treatment. The authors have called attention to the fact that stippling of the cells is by no means common to lead. Dr Foster Johns, of the department of clinical medicine at Tulane, had his attention called to a widespread mortality among wild ducks around the hunting grounds on the Gulf Coast of Louisiana. An examination of the blood of these ducks revealed the cause of the mortality. His observations were similar to those made by Dr McGrath of the Mayo Clinic a few years ago. When the gizzards of the ducks were opened it was found that they were filled with lead shots such as are used in hunting ducks. The shot removed from the gizzards were about one third the size of shot that have never been used. These ducks died from lead poisoning as a result of mistaking the shot in the bottom of the lagoons for the small stones they usually ingest. The authors have informed me that they have received the cooperation of some of the manufacturers of toys and other articles which find their way into the hands of children and have received reasonable assurance that they will use something other than lead in the paints used in coloring these articles.

DR KATSUJI KATO, Chicago. This presentation on lead poisoning reminds me of conditions in Japan. It is rather unusual in this country to see so many cases as Drs McKhann and Vogt have experienced in Boston in a period of nine or ten years, for even in Japan there is an average annual figure of about ten cases of lead poisoning in the larger pediatric clinics. I am anxious to point out that among various forms of lead poisoning there is one particular type to which but little attention has been paid in the past, namely, congenital tetanism or lead poisoning. In Japan the source of lead has been chiefly in the form of face powders. At present the government requires the use of titanium instead of lead in the manufacture of cosmetics. In spite of this lead is still being used in a certain percentage of face powders because lead seems to give a better spreading effect on the skin. The authors informed me that the pregnant mother has a greater tolerance for lead owing to the fact that the metal is taken up in the rapidly growing bones of the fetus. The Japanese mothers continuously use lead containing cosmetics on their necks, faces, shoulders and breasts during pregnancy, often to the extent of veritably whitewashing the exposed parts of the body. This would strongly suggest the possibility of congenital origin of lead poisoning in new-born infants. In certain cases of congenital hydrocephalus may it not be reasonable to suspect intra uterine lead poisoning as its cause? Again in some cases of spastic paralysis of the limbs with or without convulsive seizures which are usually thought to be due to intracranial hemorrhage, congenital lead poisoning may be a possible cause. This suggests at once that the so-called lead line at the metaphyseal end of long bones in the new-born infant presenting suggestive symptoms should be looked for by making roentgenograms. This is important both in diagnosis and in treatment.

THE ASEPTIC TANNIC ACID TREATMENT
OF DIFFUSE SUPERFICIAL BURNSDONALD B. WELLS, M.D.
HARTFORD, CONN.

Since the time of Hippocrates¹ who left detailed and complicated prescriptions for the treatment of burns probably every medical practitioner of any considerable experience has followed some favorite or original treatment of the burns that have come under his care. I am no exception to this rule. Such ideas of treatment as I have formulated are based entirely on clinical experience. I have no foundation of controlled scientific experiment to support my results, no extensive laboratory data to substantiate my beliefs, very little to prove my point, except the clinical records. I have been stimulated to present the details of this treatment through the interest taken in it not only by the staff of the Hartford Hospital, but by the Massachusetts General Hospital, where burns have been made a special assignment under the direction of Dr. Richard H. Wallace,² and the method of treatment here presented is being employed in suitable cases.

During the past decade three underlying principles have come to be recognized as of special importance in the treatment of extensive burns: first the prevention of dehydration, second the maintenance of asepsis, and, third the promotion of epithelization. The necessity of employing large quantities of water not only in the treatment of the primary shock but even more to balance the requirements of a patient continuously losing fluid day after day from an extensive granulating area was conclusively demonstrated by Underhill in 1933.³ The introduction of tannic acid by Davidson in 1925⁴ has revolutionized and apparently for the first time in history largely standardized the local treatment of diffuse burns. Secondary bacterial infection has long been recognized as an important etiologic factor in the production of the scarring and contractures that permanently disfigure the victims of these accidents, and there is increasing proof that bacterial infection, rather than proteolytic toxemia, is the cause of the progressive exhaustion terminating all too often in the ultimate death of these patients. Except in very superficial burns, epithelization is generally still secured by some form of secondary skin graft of the granulating area.

Proteolytic toxins, assumed for many years to be formed in and absorbed from diffuse superficial burns, have never been satisfactorily isolated or identified and are still altogether hypothetical. On the other hand, the serious results of bacterial infection in these burns are very real and are recognized by all. Unfortunately, it seems to have been assumed that although all burns are primarily sterile, this sterility is necessarily short lived. The conditions attendant on these accidents and the extensiveness of the lesions have heretofore insured contamination sooner or later. Dead and dying tissues

provide a most fertile soil for the growth of bacteria. Surgeons have hesitated to institute adequate measures to prevent this certain infection, because the pain associated with these accidents has made them reluctant to handle the patient, the degree of surgical shock has often contraindicated anesthesia, and debridement or epluchage in diffuse superficial burns has, of necessity, sacrificed living tissue of great value. As a result of these and, perhaps, other considerations, the fundamental basis of all asepsis, mechanical cleanliness, has been almost universally neglected, while stress has been laid on the local dressing of the burn. Because of these assumed limitations, it is not surprising that, within a few hours, all extensive burns have become more or less infected. In my experience, as well as in that of almost all other observers, many different types of bacteria participate in the production of this infection. My cultures have failed to substantiate a recent observation by Aldrich⁵ that, within a comparatively short time, the streptococcus overgrows all other organisms to become the sole possessor of the field.

Within a year of the publication of Davidson's paper Beck and Powers⁶ had noted the advantages of a spray over the wet compresses originally suggested, the desirability of rapidly drying the coagulum, and the advisability of not disturbing a firmly adherent crust even in deep burns provided infection did not develop beneath it. In uninfected third degree burns they occasionally waited reepithelization to take place solely from the periphery. I had observed these advantages in my own cases and such further modifications in the treatment of extensive burns as I have evolved are largely corollary to their observations.

I am convinced that infection alone is largely responsible for the exhausting morbidity, many of the complications and a vast majority of the delayed deaths that occur in cases of diffuse superficial burns. Other observers have come to a similar conclusion and have noted that, when infection is prevented, there is little, if any, evidence of so-called proteolytic toxemia. The method of treatment that I employ is particularly directed toward securing a mechanically clean and aseptic tin and toward maintaining this tin intact until it exfoliates spontaneously.

Instead of putting an extensively burned patient into a tent heated by electric lights and spraying him with tannic acid, I place him immediately in a tub filled with warm tannic acid solution. A good, big tub is desirable, such as is seen in the hydrotherapeutic department of every modern hospital. I am not particular about the precise percentage of the solution but use enough tannic acid powder to give it a good muddy color. Tannic acid powder is cheap and a large quantity is kept on hand and is immediately available in the emergency room. The temperature of the tub filled with tannic acid solution is regulated solely by the comfort of the patient. Fresh water is run in and the solution drained out continuously, a comfortable temperature being always maintained, and more tannic acid powder is added from time to time. I have not seen a case of tannic acid poisoning. Every adult has experienced such relief as to be thoroughly cooperative within a few minutes after being placed in the tub, semiconscious patients have seemed to sigh with relief, and others,

conscious but burned beyond possible recovery, have talked quietly and hopefully about things totally unrelated to their condition. Even hysterical little children, in the hands of a tactful nurse and under the influence of a mild narcotic, become quiet within a few minutes and passively, if not actively, cooperate in the treatment.

Once the analgesic effect has become manifest the real work begins. The solution penetrates, softens, loosens and elevates the destroyed tissue. Gross tags of full thickness skin are painlessly removed with thumb forceps and scissors, the tops of blisters are carefully and completely wiped away with gauze. Unburned areas, right up to the margin of the eschar, are gently but scrupulously scrubbed with soap and water as though the patient were receiving a bed bath. When the tub becomes grossly fouled it is drained, quickly cleaned and immediately refilled with a fresh solution of tannic acid. This mechanical cleansing goes on as long as possible—a continuous, painstaking, persistent, back-breaking effort to remove completely every bit of dead tissue and cleanse thoroughly the whole body. It is not work for a nurse in a starched uniform, an intern who knows only how to write orders or a surgeon in his evening clothes. My objective is a full three hours of continuous mechanical cleansing with the patient largely immersed in a tub full of tannic acid solution, after such a prolonged conscientious effort has been made, not only the burned area but the whole body surface is mechanically clean, while pathogenic bacteria with their necrotic pabulum have been practically eliminated.

The tub filled with warm tannic acid solution possesses all the advantages and virtues extolled by the advocates of the immersion treatment of burns during

Fig 1—Patient largely submerged in tub of tannic acid solution in which mechanical removal of sloughs and blisters and thorough cleansing of the entire body is accomplished.

the past thousand years or more. It facilitates the removal of burned clothing and debris, the patient is scrupulously cleansed from head to foot, accruing products of inflammation are promptly washed away, the anodyne effect is surprisingly immediate and complete, body heat is constantly maintained, it is a recognized method of combating surgical shock, and the

burned areas tan rapidly. Throughout this period of mechanical cleansing as much fluid as possible is given by mouth—water, coffee, orange juice—whatever the patient will take in greatest abundance, for dehydration must be prevented.

By the time the patient is clean and ready to leave the tub, the tan is already established. It is an unusually smooth, thin, adherent coagulum, for all

Fig 2—Completely exposed patient being repeatedly sprayed and immediately thoroughly dried.

foreign material, gross sloughs and blisters have been removed in the tub and the chemical penetrative powers of the tannic acid have not been dissipated in the fixation of such dead tissue as could and should be removed mechanically.

At this point I employ the second distinctive feature of this treatment. The patient is transferred from the tub to a warm room, placed on a dry bed and, from this time on, kept absolutely dry with a continuous draft of warm air from one or more large commercial hair driers. These machines are so constructed as to permit a wide range of choice in the velocity and temperature of the draft they furnish. Heretofore it has been usual to place these patients in a tent heated by electric lights, but such a contrivance cannot compare with the blower for either comfort or efficiency. The burned area and, preferably, the entire body is fully exposed to the warm draft from the blower. For about seventy-two hours after the patient has been removed from the tub, the burned areas are more or less constantly sprayed with a 5 per cent solution of tannic acid but immediately and thoroughly dried with the blower. Only a small area is sprayed at a time, this is completely and absolutely dried before another area is sprayed. The bed is never allowed even to become damp. I am very careful that every little blister that may form during this period is carefully wiped away with sterile gauze, sprayed and immediately dried. Such little blisters represent inflammatory products from cells which though they may have survived the immediate trauma were so grievously injured that they died after the removal of the patient from the tub. They almost invariably appear at the periphery of the developing eschar.

The eschar is usually perfectly firm and adherent after seventy-two hours of alternate spraying and immediate thorough drying. Thereafter new blisters seldom appear. From this time on the blower alone is

employed, but the draft of warm air must be maintained continuously, for it is of the utmost importance that the still completely exposed patient be kept absolutely dry. Even a little perspiration may soften the precipitate and a macerated tan invites bacterial invasion. If infection supervenes, the eschar will separate and require removal, being replaced by a granuloma which, in all probability sooner or later will require skin grafting under relatively unfavorable conditions.

The method of treatment that I have outlined, the securing and maintenance of an aseptic eschar, is applicable to the great majority of burns requiring treatment in a general hospital. It is a method of treatment especially useful in extensive scalds and in such burns as result from gasoline explosions or ignited clothing. It will be most successful in those diffuse superficial burns in which little scattered islands of epithelium survive, such as hair follicles and sweat glands, from which, under the protection of an aseptic tan, reepithelization rapidly takes place. I have not had to resort to skin grafting of any sort in a single scald treated by this method, and I am inclined to believe that reepithelization in every diffuse superficial burn may be more nearly perfect and leave less scarring when it is developed under the protection of an aseptic tan than when it is promoted from any form of a skin graft.

This method of treating diffuse superficial burns, based on securing and maintaining an aseptic eschar, can be carried out most successfully in a well equipped hospital. The necessary physical equipment can be easily assembled there, ready for immediate use. In the order of its employment, this equipment consists of an oversize tub, an adequate available supply of tannic acid powder, a properly ventilated room that can be maintained at an even temperature, day and night, a small hand atomizer and an electric hair drier. The most essential requisite, however, is an immediately available personnel of not less than three intelligent and enthusiastic nurses who thoroughly understand the principles on which this treatment is based. Whatever success I may have attained with this method of treating extensive superficial burns is due to the intelligence, enthusiasm and loyalty of a small group of nurses. Failure is certain when the fundamental principles are not grasped or when there is a distaste for continuous physical exertion on the part of hospital personnel.

I have secured and maintained asepsis of diffuse superficial burns by this method of treatment. This I have proved repeatedly by obtaining sterile cultures from beneath an eschar developed and maintained by the method here described. On the other hand, every failure to secure and maintain an adherent coagulum to complete reepithelization has been associated with bacterial infection. To paraphrase Moynihan: "The treatment of every burn is an experiment in bacteriology." The success of the experiment in respect of the salvation of the patient, the quality of healing in the wound, the amount of local or constitutional reaction, the discomforts following the receipt of the burn, and the nature and severity of any possible sequels depend on the intelligence and the constant care exercised by those in attendance.

580 Asylum Street

RECONSTRUCTIVE SURGERY AND OLD FACIAL BURNS

HOWARD L. UPDEGRAFF, MD
HOLLYWOOD, CALIF.

One of the first demands for reconstructive surgery came through the necessity of repair of old facial burns. The custom in early warfare of pouring boiling pitch over the walls onto the invading host doubtless furnished many cases. The last war evolved certain surgical procedures now in general use: the Stent graft (Escher's outlay), the perfection of the tube flap and the popularization of larger skin grafts.

The present-day machine age has so greatly multiplied the number of burned faces that they are more numerous today than they were in war time. There is now more opportunity to study these cases, as they are usually carried through to reconstruction in one hospital. Constant observation of these cases over several years has brought new emphasis on methods of determining scar causation and treatment.

The cause of the burn is not particularly important as reconstructive surgery is not advisable until the tissue is fully recovered from the insult. An inventory of the amount of destruction in old facial burns should list first the injury to the various sense organs. The depth of the burn and the possible inclusion of cartilaginous and bony structures must be evaluated. The amount of hair-bearing tissues destroyed is important from a future cosmetic point of view. The burn may be so extensive as to preclude the use of the surrounding tissue for sliding flaps or tubes.

The good tissue remaining is difficult at times to identify, owing to the pull of surrounding cicatrices. The lower eyelids may be spread down over the cheeks in such pronounced ectropia as to seem obliterated. The nostrils may be sealed over and the lips adhered to the nose or even the chest. Apparent absence of the upper part of the ears may prove to be nothing more than that they are embedded in the scar tissue.

The scarred tissue varies greatly in appearance. Induration and scaling indicate that healing is still active. The tendency to seborrhoeic reddish, hard keloids is indicative of continued irritation, either bacteriologic or perhaps due to the original burning agent, and is a danger sign of grave importance.

A point too little stressed in the treatment of facial burns is the extremely poor mental attitude of the patients. They feel that theirs is a hopeless fate, and their reaction is reflected in their general physical condition. Their disinclination to care for themselves renders them prone to kidney and lung involvement.

The necessity of preserving the special sense organs may advance the date of reconstructive surgery before the original burns have healed. A single case may and often does present a gamut of complications that range from corneal ulcerations to missing or adherent ears. Entropion, ectropion, external nasal obstruction, oral constriction, painful cicatrices, orbital deficiencies, exposed bone and marked keloidal involvement may call on early repair necessitating the application of the principles of reconstructive surgery. The presence of any of these complications implanted on a diseased body materially advances the importance of each.

The plan for reconstruction of the burned face is aided by recourse to old and new photographs and plaster face models built up to meet natural contours. The problem may then be divided into surgical stages and the time element scheduled. The character and number of skin grafts indicated as well as the possible use of tube flaps and the territory of their origin, must be planned.

The preservation of the eyes usually involves the restoration of the lids. My associates and I have used the Stent graft (Esser outlay) in about 70 per cent of our cases. This consists of dissecting the scar adhesions free from the lid and implanting a thin skin graft, wrapped raw side out, around a modeled piece of Stent or dental impression compound. The Stent is removed in from five to eight days, leaving a sulcus which smooths out from the surrounding tissue tension in from four to six weeks.

Controversy exists as to the best means of eyelid reconstruction. If thick skin is needed, it should be provided by flaps. The conjunctival deficiency may be supplied by lining the projected eyelid flap with mucous membrane from the oral cavity.

To protect the eyes, glasses with Crookes lenses must be worn. Adhered ears from scar tissue must of necessity be freed and permanently raised to hold the spectacle bows. The top of the ear is usually the most severely burned, owing to the proximity of the hair. The employment of a large Stent graft with the introduction of a small tube flap later on to furnish the ear rim gives a satisfactory ear.

Generally speaking, the release of major scar adhesions of the burned face may be best accomplished by free undercutting and the advancement of a tube flap from the nearest available area. The tube may be waltzed to the points of greatest tissue distortion and a sufficient amount of full thickness skin from the tube left to fill the defect from the surrounding scar tension. This principle of assignment of portions of the tube to different sites has not received sufficient notice in contemporary literature. As an example, many times in severe burns of the face the nasal arch is obliterated by scar contraction, and the inner canthus is pulled up to the level of the nose. The placement of a full thickness graft with the necessary ten to fifteen day pressure presents a problem of definite proportions. The employment of one end of a small tube flap solves the difficulty.

The transference of the remainder of the tube flap, for instance to the upper lip, necessitates only the rotation of the tube to the lip allowing the blood supply to continue from the original source. The philtrum may be reconstructed by dimpling the respread flap in the center line by catgut sutures inserted between the outspread tube and the lip. If alar deficiencies exist, a small curtain flap may be elevated from the tube while on the upper lip to furnish the necessary tissue. The scar tissue flap from the ala is lowered to cover the raw area from the tube.

The eyebrows may be reconstructed by the use of full thickness 5 mm wide grafts from the scalp. The use of hair-bearing grafts for eyelashes is acceptable only in the absence of a history of corneal ulceration.

The use of full thickness grafts on movable portions of the face offers a problem owing to the hardship of attempting immobilization and necessary pressure. This may be solved by the use of the intradermal graft or the use of a half or a full thickness tunnel graft when relief of marked contraction is desired.

The greatest factor in reconstructive surgery of the burned face is the forbearance to wait between operative stages until the tissues heal and soften. The intervals between surgical steps are aimed at the furtherance of these conditions.

The patient's mental condition may be markedly improved by instruction in the use of makeup. It is my custom to employ a professional makeup artist to aid in giving the patient a vision of the final result. The boon works both ways as the more difficult points of makeup usually mark the important features of the operative stages.

Even with carefully planned surgery our efforts may go astray if attention is not paid to the underlying factors influencing healing. In our experience, routine preoperative laboratory work, such as urinalysis, blood work including red and white counts, differential bleeding and clotting time and a Wassermann test are a necessity. From the point of view of purely reconstructive plastic surgery, our greatest laboratory interest is in the basal metabolic reading. Without exception in a large series of burned patients with keloidal scars we have found a markedly low metabolic reading. I believe that the increased concentration of the blood over a long period following large burns, produces a partial asphyxiation of the tissues, which permanently damages the mechanism controlling the metabolic rate. The administration of thyroid substance by mouth has markedly improved the keloids under our observation and in certain hypertrophic scars has been almost specific.

With this thought in mind, the once generally accepted fact that keloids occur only in Negroes creates an issue. The fact is that in the Northern, so-called goiter states, few keloids occur in native-born or old inhabitants. In the South, where goiter, by comparison is seldom seen, keloids are common. A recent conference with the medical officers of the Japanese training fleet visiting in Los Angeles brought forth the information that keloids are literally unknown in Japan where the diet is high in iodine content. These are broad generalizations, made purely with the thought of raising the question as to whether the presence or absence of hypertrophied scars and keloids may not be partially a glandular dyscrasia.

As a routine in the clinic with which I am associated Rosenau tissue cultures of excised keloidal material are made. Dr. Herman Zeiler, the pathologist has isolated in a number of instances, a staphylococcus type of organism. A bacteriophage made from these organisms when used as a local application on the wounds of the patient from whom the organism was isolated seemingly prevented further keloidal formation. Injection of the bacteriophage into keloids on other parts of the body of the patient caused sloughing and subsequent marked improvement of the area injected, in from six to eight weeks. It is possible that a low grade infection sealed in the tissue of an old healed burn in a patient with either a lowered metabolic rate due to the burn or a low metabolic rate before being burned offers a reason for keloidal and hypertrophic scars.

The use of the x-rays in the treatment of old facial burn scars at our hands resolved itself into the early treatment of new surgical scars contracted in the improvement of the old ones. Our radiologist Dr. B. H. Sherman has good results by the use of the Leco air-cooled tube with the broad focus. A dosage of 100 kilovolts with 4 milliamperes giving 550 roentgens measured in air through 1 mm of aluminum over

four weeks, has been helpful in the treatment of soft recent keloids. If more advanced and with marked induration, we abandon the filter.

The path of the surgeon engaged in reconstruction of the burned face has been materially shortened by the use of the Guedel-Watters endotracheal anesthesia technic.

SUMMARY

1. Reconstructive surgery of old facial burns should be avoided if possible until complete healing has taken place.

2. The possibility of loss or impairment of various special sense organs may necessitate earlier surgery.

3. Adherent eyelids, nasal contours and ears are best released by use of Stent grafts.

4. Release of major contractions in areas difficult to immobilize and dress correctly may be accomplished by the use of intradermal grafts, tunnel grafts and small tube flaps.

5. The basal metabolic rate should be checked and, if low, thyroid medication should be forced.

6. Autogenous bacteriophage therapy is helpful if positive Rosenau tissue cultures can be made.

7. Early roentgen therapy is of benefit following surgery.

8. Endotracheal anesthesia is the method of choice in the reconstruction of old facial burns.

6777 Hollywood Boulevard

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. S. J. SEEGER AND DR. WELLS

DR. S. J. SEEGER, Milwaukee. The suggestion of Dr. Wells of combining the tannic acid treatment with the immersion treatment seems sound and offers one more facility in aiding these patients. Tannic acid solutions used clinically are strongly acid and highly astringent. Experimental work which I have done indicates that these solutions tend to cause swelling and edema of the tissues and a too rapid fixation of tannin at the surface. This is in accord with the experience of chemists in the leather industry. These disadvantages are overcome by neutralization to the same pH value as that of the blood. This neutralization is accompanied by no loss in tanning power. Clinical experience indicates that the previously observed beneficial effects of tannic acid are retained. Underhill demonstrated that loss of water is one of the important clinical factors in extensive burns. It is conceivable that the edema produced in the tissues by acid solutions of tannic acid may enhance the amount of water lost into the burned areas. In working out the technic of Dr. Wells, it should not be difficult to arrange to maintain a solution of fairly uniform percentage and pH value. My experience in the treatment of 300 burned patients indicates that there is no harmful effect on the normal skin adjacent to the burned area as a result either of spraying the surface or using wet packs of tannic acid. In the tanning industry men not infrequently fall into tubs of tan liquor and wear clothing and boots for many hours that are wet with tanning solutions. No studies have been made of these individuals but aside from the discoloration of the skin there is apparently no deleterious effect. Chemists do not agree on the best method of quantitative determination of tannin. The assumption that chemically pure tannic acid which is expensive contains nearly 100 per cent of tannin is incorrect. The so-called cutch, quebracho and wattle extracts in the group of commercial catechol tannins contain about 60 per cent of tannin. This is comparable to the amount of tannin contained in chemically pure tannic acid. The catechol tannins are inexpensive so that the amount to be used to make a 5 per cent solution in 100 gallons of water would cost only a few dollars. The rate of tanning varies with the extract and is important as it may well have an effect on the fate of some patients. I wish to warn against the error of assuming that any one method of treating burned areas solves all the problems associated with burns. The tannic acid method has many advantages but

much work remains to be done particularly for the patient with extensive granulating wounds and a low grade infection, who may be carried through the initial period of shock only to succumb later of exhaustion.

DR. FERRIS SMITH, Grand Rapids, Mich. The clinical results detailed by Dr. Wells in the use of the tannic acid bath in recent burns, and the equally excellent functional and cosmetic results demonstrated by Dr. Updegraff in the management of healed facial burns presenting the various accompanying tissue losses and contractures, merit approval. Dr. Wells emphasizes the three cardinal requirements in the management of extensive burns. Two of these are vitally essential and the third is usually a corollary. He has developed to a fine degree the use of a commonly employed agent which seals the surface to prevent dehydration and which maintains an asepsis so vital to the recovery of the patient. The keynote of his success is thoroughness and meticulous attention to every detail. His conception of proper care of these patients is a distinct contribution to emergency therapeutics. I agree in principle with most of Dr. Updegraff's discussion. His remarks relating to keloid and hypertrophied scar are an interesting innovation. His theory of the etiology and suggestion as to management will be eagerly considered by many practitioners. Sheehan advanced the theory that keloid is due to disturbance of the lymphatic circulation and obtained some results from the use of setons to establish new channels. He has also obtained some excellent results from the temporary implantation of radon along the edges of the incisions in cases in which operation has been performed. I would suggest the daily use of diathermy for minimum periods of one hour to hasten scar absorption and to improve circulation. This effort pays big dividends in producing better tissues and shortening the time of completing the repair. I cannot agree that the employment of the so-called Esser outlay for lid repair is the method of choice in the majority of cases. This was the best method available during the last two years of the war. Subsequently, John Wheeler contributed a technic employing points of temporary adhesion of the lids during scar organization and a split skin graft giving a smoother result. I use this method with full thickness grafts from another lid or the back of the ear. Dupuy-Detemps describes an excellent method of restoring a lid with all its normal elements except muscle.

DR. D. C. ENLOE, Sherman, Texas. The control of absorption of the toxic substance that is given off in the case of a burn was illustrated to me in a patient in whom more than half the body was burned. He was an electric lineman who received a charge of 60,000 volts. The clothing was burned from him, resulting in second and third degree burns of the entire right arm and the body from the neck to the bottom of the buttocks, extending two-thirds round the body and down the left arm to the elbow, and from the hip to below the knee entirely encircling the left leg and destroying the muscles on the outer aspect of the leg. Tannic acid treatment rendered the patient so comfortable that but little opiate was required. After the tanned skin and tanned muscles began to come away, debridement was done, but then there was another factor to combat—infection. Treatment instituted in this particular case convinced me that absorption from infection can be controlled by the use of wet metaphen dressings, 1:5,000. Boric acid dressings in such cases will produce toxemia, dressings with surgical solution of chlorinated soda will irritate healthy skin, saline dressings will not control the infection but wet metaphen dressings applied will clear up the infection. The grafts may be applied early on healthy granulating wounds, and the wet metaphen dressings 1:5,000 are continued until the lesions are healed. The grafts will grow faster, high granulations will not develop, scar tissue will be minimized, and good cosmetic results will be obtained.

DR. DONALD B. WELLS, Hartford, Conn. I have been interested in electrical contact burns. They are entirely different from these diffuse superficial burns which I have discussed. Electrical contact burns are always exceedingly circumscribed and are relatively deep and often it is possible to extirpate an electrical contact burn completely and do either an immediate suture or an immediate skin graft. I have had a large number of electrical contact burns. This form of treatment has proved most successful. I suggest that it be tried in suitable cases.

CARE OF ADVANCED CARCINOMA OF
THE GASTRO-INTESTINAL TRACT

FRANK C YEOMANS, MD

NEW YORK

In the United States more than 100,000 persons die annually from malignant disease. The death rate for cancer throughout the country per hundred thousand of population was 63 in 1900 and 96 in 1929, an increase of 52 per cent. Cancer ranked sixth as the cause of death in 1900 and rose to second place in 1930.

At the twenty-second annual clinical congress of the American College of Surgeons held at St. Louis in October, 1932, a symposium was presented on the curability of cancer. Crile¹ reported that 4,059 patients seen at the Cleveland Clinic prior to 1928 had been traced. Of 726 patients seen with carcinoma of the stomach, thirteen survived operation three years and seven a period of five years, that is, a survival of 2.7 per cent of all patients seen. Of 841 cases of malignant tumors of the colon and rectum seen, eighty-nine patients survived for three years and forty-eight for five years, or 16 per cent of all cases seen.

Gatewood² reported that, in the ten year period 1920-1929, 417 patients were discharged from the Presbyterian Hospital in Chicago with the diagnosis of carcinoma of the stomach. Exploration was done in 209 of these. Thirty per cent were considered radically operable. Resection was done in fifty-eight cases with an operative mortality of about 18 per cent. Of the patients who survived operation, 46.1 per cent lived more than three years and 39.5 per cent lived more than five years. This is an operative survival of from three to five years, or 4.2 per cent of all patients seen.

These recent and authentic follow-up statistics serve to emphasize again the fact that the great majority of patients with a malignant condition of the gastrointestinal tract still reach the surgeon in a stage of the disease so advanced that radical excision—the most hopeful type of therapy—is impossible. From the very nature of conditions it would seem that this state will persist and that palliation will consequently continue to be the only form of treatment for the overwhelming number of patients with carcinoma of the gastrointestinal tract, for the following reasons:

1. In many instances the malignant process is insidious in onset and almost symptomless until far advanced or the patient all too frequently neglects early warnings.
2. Failure to make a thorough examination when medical advice is first sought is quite common.
3. There are difficulties in detecting and it is frequently impossible to detect early malignancy in certain situations by available methods of diagnosis.

SYMPATHETIC ATTITUDE

Unfortunately many physicians assume an attitude of despair toward the patient with advanced cancer. Thus the victim of inoperable cancer becomes the forgotten man in the medical world and may quickly fall a prey to the irregular practitioner or quack. While it is true that a cure is seldom to be expected and their management is difficult and irksome, yet these hopeless sufferers deserve all the care and comfort that modern science affords. To neglect them is to acknowl-

edge defeat without due appraisal of the agents of relief at one's command. The desideratum is life in comfort while it lasts, not merely an uncomfortable existence.

SUPPORTIVE MEASURES

Essential are nourishing food of high caloric value, good hygiene and competent nursing together with rest and sufficient sleep obtained as necessary, by sedatives, analgesics or opiates. Tonics of iron and arsenic are indicated and in some cases whisky in 1 ounce (30 cc) doses, transfusions of blood, cod liver oil with viosterol and once or twice weekly an ampule of calcium gluconate by vein, which, according to some clinicians, in large continued dosage is a potent analgesic. If the blood Wassermann reaction is positive antisyphilitic treatment is given.

MATERIAL

During the period of nine years from its organization in 1923 to and including the year 1932, 10,070 patients have been admitted to the New York City Cancer Institute, a division of the Department of Hospitals of New York City. These figures are shown in the accompanying table. The incidence of gastro-intestinal malignant conditions included esophagus 192, stomach 622, colon 77, sigmoid 70, rectum 406, anus 17. All cases involving the gastro-intestinal tract constituted 1,384 or 13.7 per cent of total admissions.

Only a small percentage of these cases are radically operable on admission. Many of the patients have had surgical or radiation therapy elsewhere and are received into the hospital for custodial care. As the institute is municipal, no patient is denied admission. Consequently a large field for palliation is available.

Read before the Section on Gastroenterology and Proctology at the Eighty-fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

1. Crile, George. Surg. Gynec. & Obst. 76: 417 (Feb. 1, 1933).
2. Gatewood, M. A. Surg. Gynec. & Obst. 76: 442 (Feb. 1, 1933).

Except when obstruction, as of the esophagus, pylorus, colon or rectum is the cause, cachectic patients are barred from any type of active treatment, such as irradiation or surgery, and efforts are limited to the simplest measures of relief.

CARCINOMA OF THE ESOPHAGUS

Carcinoma of the esophagus comprises from 2 to 8 per cent of all cancer cases. The majority of these patients are men over 45, the incidence being six males to one female. The approximate location of the lesion in the esophagus is upper third, 20 per cent, middle third, 30 per cent, lower third, 50 per cent. Carcinoma constitutes about two thirds of all disease of the esophagus, and in cases that come to autopsy over 60 per cent show invasion of neighboring organs or metastases. Histologically, from 65 to 85 per cent of the neoplasms are squamous cell, the remainder being transitional cell type and adenocarcinoma. Moreover, grading of biopsies from squamous cell carcinomas of the esophagus indicates that, theoretically at least, 20 per cent or less are sensitive to irradiation.

The cardinal symptom of carcinoma of the esophagus is progressive dysphagia. The stenosis may finally reach the stage in which not even water can be swallowed, and the patient rapidly becomes emaciated and dehydrated—is being literally starved to death.

DIAGNOSIS

The history, the Wassermann test of the blood and a competent roentgen study establish the diagnosis and differentiate cancer from other obstructive lesions, such as cardiospasm, cicatricial contracture from caustics, syphilis, a diverticulum or external compression. If grave doubt exists as to the nature of the lesion, esophagoscopy is done and biopsy.

Clinicians are agreed that gastrostomy should be performed as soon as solids will not pass the stenosed lumen and nutrition begins to fail. "Early gastrostomy insures sufficient nourishment for prolonging life comfortably during radiation while the body is still capable of recuperation" (Kaplan). As a rule, we do the Janeway type of gastrostomy under local anesthesia. The goose-neck formed from a pedicle flap raised from the anterior wall of the stomach is fixed into the upper angle of the epigastric incision or is brought out through a stab wound to the left of the primary incision. A size 14 F catheter is inserted for feeding only, and there is practically no leakage from the stoma. In urgent cases or when only a small area of sound stomach is available, a Senn gastrostomy may be quickly established and is quite satisfactory. Mortality from these operations is very low. If the patient is dehydrated, it is important for him to receive dextrose in physiologic solution of sodium chloride by hypodermoclysis before operation.

As soon as the patient has recovered from the operation and the condition has been controlled by a regular check-up of the blood picture, protracted high voltage roentgen irradiation is directed to the area of the lesion. It is difficult to evaluate this form of therapy, but I feel that it is of definite benefit in relieving pain, has a favorable psychologic effect and possibly slows the malignant process.

A properly performed gastrostomy with subsequent adequate feeding works a dramatic improvement in a large number of cases. Gain in weight, improved morale and relief of symptoms enable many patients to live several months in comparative comfort.

We have not used radium within the carcinomatous lumen of the esophagus of patients with advanced disease, feeling that the ordeal and trauma (possible hemorrhage or perforation) caused by its application would do more harm than any possible benefit that could reasonably be expected. However, Guisez³ reported that of 270 patients treated with radium within the esophagus, thirty lived more than eighteen months. No evidence of a malignant growth was present in twelve of these patients after more than eighteen months, in four after three years, in four after four years, and in one each after five, ten and eleven years. Presumably the lesions in his cases were not of the advanced type under discussion.

CASE 1—J. M., a white man, aged 54, complained of progressive dysphagia until not even water could be swallowed when he was admitted, Sept. 20, 1932. He was anemic and emaciated and regurgitated all food and fluids. Roentgenograms showed a defect typical of a malignant condition in the lower third of the esophagus and an aneurysm of the aorta. The blood Wassermann reaction was 4 plus. Hypodermoclyses of dextrose in saline solution were administered. Gastrostomy performed, September 22, was followed by high voltage roentgen therapy over the mediastinum, anterior and posterior, and antisyphilitic treatment was administered. The patient improved rapidly, gaining 20 pounds (9 Kg.), and was very comfortable for four months. Then he deteriorated rapidly until he died, March 4, 1933.

CARCINOMA OF THE STOMACH

The stomach is the commonest site of carcinoma in the digestive tract. It is noteworthy that some patients have very few symptoms until the lesion is far advanced. Owing to its inaccessibility, early detection of gastric involvement with malignant disease is most difficult. Our chief reliance for diagnosis is fluoroscopy and roentgenograms. Gastrostomy is also a useful measure in the rare case of carcinoma of the cardia, but the majority of advanced cases develop obstruction at the pylorus and are radically inoperable. In these circumstances we usually perform gastro-enterostomy and, if deemed advisable, implant gold seeds of radon into the malignant area. This gives a high degree of palliation and is well worth the effort.

CASE 2—M. Y., a white woman aged 58, married, admitted Oct. 31, 1925, complained of indigestion and epigastric pain. She was well nourished, not anemic and a nodular mass was present in the epigastrium. A roentgen examination showed an irregularity of 3 cm. along the greater curvature of the stomach, the pars media with failure of visualization of the pyloric portion for a distance of 5 cm. At two and six hours a residue of one fourth of the meal was proximal to the lesion. Exploration, November 10, showed that the neoplastic involvement was as extensive as the roentgenograms indicated. A posterior isoperistaltic gastro-enterostomy was done and after biopsy, which showed adenocarcinoma, fifteen seeds of 0.3 millicurie of radon each were implanted into the neoplastic area.

On discharge, Jan. 24, 1926, the patient had made an uneventful recovery from the operation, had gained in weight and had been practically symptomless. Five months later she was eating well and maintaining her nutrition, but the tumor mass was extending. In September, 1928, she died from the malignant growth at her home two years and ten months after coming under treatment.

CARCINOMA OF THE COLON

Disturbance of bowel function and progressive constipation are the leading symptoms of carcinoma of the colon, particularly with involvement of the splenic flexure and the rectosigmoid, two naturally narrow

³ Guisez, J. Bull. et mem. Soc. med. d. hop. de Paris 47: 908-917 (June 1) 1931.

points. Indeed, acute obstruction is the first definite symptom in some cases. Increasing secondary anemia is characteristic of involvement of the cecum.

Important aids in diagnosis are a "scout" x-ray film, fluoroscopy while the barium suspension is being administered, employment of the combined method of Fischer, whereby films of the colon are taken after partial evacuation of the opaque enema and inflation of air, and proctosigmoidoscopy.

If other measures fail in the presence of acute obstruction, cecostomy of the Witzel type, done under local anesthesia, affords prompt relief by decompressing the colon until exploration can be safely undertaken.

Palliative surgery virtually resolves itself into short-circuiting operations or colostomy. For radically inoperable carcinoma of the cecum and ascending colon, ileocolostomy (distal ileum to the transverse colon) is indicated. For obstruction of the transverse colon by a neoplasm, possibly involving the stomach, the approved procedure is cecosigmoidostomy or better, end-to-side ileosigmoidostomy and fixing the distal loop of ileum into the wound as a stoma to prevent stasis within the short-circuited loop.

Short-circuiting of an irremovable tumor of the splenic flexure or descending colon is most easily effected by a lateral anastomosis between the transverse colon and the sigmoid.

CASE 3—C. H., a white woman, aged 57, married, admitted Dec. 6, 1930, complained of acute intestinal obstruction. She was anemic and emaciated and was belching gas; the abdomen was so tensely distended and tympanic that palpation was unsatisfactory. Immediate cecostomy decompressed the colon and thirteen days later at laparotomy the descending colon and mesenteric lymph nodes were found to be involved in an extensive, fixed adenocarcinoma. The transverse colon was united to the sigmoid by a broad lateral anastomosis. The patient regained weight and strength and lived in comfort until January, 1932, a period of fourteen months, when ascites and other signs of general abdominal carcinosis developed to which she succumbed at her home ten months later.

CARCINOMA OF THE SIGMOID

The sigmoid flexure is the site of greatest incidence of carcinoma in the large bowel. In this situation it must be differentiated chiefly from diverticulitis by competent roentgen study. Slightly over 2 per cent of cases of carcinoma of the sigmoid are associated with diverticulitis. This small percentage suggests that the relationship is incidental and not causal. However, bleeding in diverticulitis is a rare symptom which I have observed in only three cases, so when hemorrhage occurs in a patient known to have diverticulitis a malignant condition should be suspected.

Because of its favorable anatomy, carcinoma of the sigmoid is usually amenable to radical surgery. If extensive peritoneal involvement or other metastases preclude this procedure, colostomy should be established in the transverse colon. It is an important working rule to make the artificial opening at a safe distance from the tumor lest the stoma become involved in the neoplasm.

CASE 4—N. S., a woman, aged 60, unmarried, admitted Sept. 12, 1930, complained of constipation pain in the left lower quadrant of the abdomen and swelling of both legs and ankles due to varicose veins. Her general condition was fair. An adenocarcinoma occupied the anterior fourth of the bowel wall beginning 5 inches above the surface of the skin and extending upward 2 inches into the pelvic colon. Radical operation was refused. To date the patient has received five courses of high voltage roentgen therapy and two applications of radon. Two

polypoid tumors, one at the 6 and the other at the 8 inch level, have been removed by the electrical snare passed through a proctoscope. Both of these tumors were adenocarcinoma. At present two and one half years after beginning treatment, the patient is free of symptoms and there is no local evidence of activity of the carcinoma. She is in good health and works regularly as a laundress.

CARCINOMA OF THE RECTUM

Next to the stomach, the rectum is the commonest site of carcinoma of the alimentary canal. Although digital palpation and sigmoidoscopy, with biopsy in doubtful cases, establishes the diagnosis in practically all cases of malignant conditions involving the recto-sigmoid and rectum proper, many patients still reach the surgeon too late for radical excision. Unfortunately, this is frequently due to reliance on an indirect roentgen study which visualizes poorly early lesions of this bowel segment within the pelvic girdle instead of palpation and direct inspection of this accessible field.

When obstruction is present or frequent discharges are annoying and depleting in radically inoperable cases, colostomy under local or spinal anesthesia is indicated, is most beneficent and affords an avenue for effective irrigation. The loop type of colostomy is usually established through the left rectus muscle, as it is simple of execution, requires little manipulation and bears practically no mortality. A colostomy under dietary control is much less objectionable than is popularly believed. The wearing of a receptacle should be avoided if possible.

A cycle of high voltage roentgen therapy is frequently successful in checking rectal hemorrhage, sometimes even retarding the progress of the disease. The rays are applied through two anterior and two posterior pelvic portals and a perineal field. Each area receives a total of from one to one and one-half erythema doses, one-fourth dose per treatment. Governed by the condition of the patient, one or two areas are irradiated daily.

RADIUM

The institute possesses 2 Gm. of radium in solution and 40 mg. in element. In most instances radon is used for treatment, in either gold seeds or platinum tubes and needles. Treatment is given by surface applicators made up of tubes or in cases of carcinoma of the rectum the tubes are inserted within the malignant bowel lumen as a tandem in a tube of pure rubber or when the lumen is sufficiently large with a proctostat. When accessible the tumor is treated most satisfactorily by interstitial seed implants inserted directly by trocar. In reckoning dosage it is generally considered that the effective irradiation of the implants is three times that of an equal amount of radon applied to the surface, i. e. intraluminal.

A small intraspinal dose of procaine hydrochloride (from 40 to 70 mg.) is a most satisfactory form of anesthesia.

After the reaction from the irradiation has subsided the tumor in many instances shrinks noticeably or is held in abeyance, the discharge is reduced and the pain is relieved all for varying periods.

CASE 5—D. T., a white man, aged 57, admitted Nov. 11, 1930, for one year had noted rectal bleeding which had increased markedly during the last four months. He was slightly anemic but otherwise in good condition. The lateral and posterior walls of the rectal ampulla were infiltrated with a large fixed adenocarcinoma. Following sigmoidostomy he received high voltage roentgen therapy and intraluminal implants of radon. He was ambulatory, was practically symp-

tom free, and maintained good health until February, 1933, when pelvic pain developed. A subarachnoid injection of 1 cc of absolute alcohol administered, March 3, promptly relieved this symptom and the patient continues in good general condition, two years and six months after beginning treatment.

EPITHELIOMA

Epithelioma of the anus is comparatively rare. It usually arises in the mucocutaneous lining of the anal canal, but occasionally it may develop at the opening of an old fistula or in operative scar tissue. It is generally of the squamous cell type and tends to encircle the anal canal early and to infiltrate beyond its margin. Metastasis is commonly through the perineum to the inguinal lymph nodes. Differentiation of this exquisitely painful lesion is to be made chiefly from indurated fissure (biopsy) and primary chancre (dark-field examination for *Spirochaeta pallida*). The preferable method of treatment of this highly malignant neoplasm is irradiation by intratumoral seed implants of radon. In some cases radical excision should be done from six to eight weeks after the beneficial effects of the irradiation have been obtained. The inguinal lymph nodes are treated by applicators of radium and high voltage roentgen therapy. Neglected cases may require colostomy in addition to irradiation for the relief of pain.

ELECTROSURGERY

The high frequency cutting current is a new and valuable agent with which to combat cancer. The quickest and most satisfactory relief for a large fungating growth of the rectum, which protrudes and involves the perirectal tissues, is to ream it out with electrosurgery and then implant the wound at regular intervals with gold seeds of radon. The palliation resulting is well worth the effort.

PAIN

To the lay mind, carcinoma denotes pain. This may be true or not, depending on the location of the tumor and the structures involved. In malignancy of the gastro-intestinal tract pain is usually a late symptom except in many cases of carcinoma of the stomach and almost always in epithelioma of the anus. This is unfortunate, for were it an early manifestation, patients would seek relief at an earlier phase of the disease.

Pain in the chest is a common complaint in advanced carcinoma of the esophagus. It is due more to the stasis of food and fluids above the constriction than to the tumor. Proof of this is the marked relief following gastrostomy. High voltage roentgen therapy seems also to exert an analgesic effect.

Gastric pain is frequently allayed by drugs possessing a local anesthetic or an analgesic effect, such as ethyl aminobenzoate or orthoform. When other measures fail, morphine or dilaudid (dihydromorphinone hydrochloride) in adequate dosage as needed becomes the sheet anchor.

INTRASPINAL ALCOHOL FOR PAIN

In 1931, Dogliotti⁴ proposed subarachnoid injections of absolute alcohol for relief of peripheral pain, employing it in forty-five cases with marked relief. Recently he visited the institute and kindly demonstrated his technic to us. For visceral and abdominal pain injection may be made between the first and second lumbar vertebrae. With the patient resting on the side opposite to that affected, the alcohol in a tuberculin syringe is injected very slowly, drop by drop a

total of from 0.2 to 1 cc, varying with the nature of the case. The patient remains in this position for twenty minutes and then is rolled on his back, where he rests for two hours. Following the injection, zones of anesthesia or hyperesthesia may appear, and cutaneous or tendon reflexes may be diminished or lost. The motor effects are mild but temporarily the knees may bend under the patient when he stands or tries to walk. These phenomena disappear in a few hours or, at most, days. Usually there is no disturbance of bowel or bladder function, although in one of our cases there was retention of urine.

If the pain is not relieved in a fortnight the injection is repeated at the same level of the spinal cord, but with the patient resting on the opposite side. The rationale of the treatment is that absolute alcohol, being lighter than the spinal fluid, rises and follows the line of exit of the spinal nerves, hence the necessity of keeping the patient immobilized for some time after the injection. The spinal fluid is at first under increased pressure and the cell count is increased, but it returns to normal in ten days. The relief of pain on the average lasts for six months.

We have employed the method with gratifying results in seven cases of malignancy presenting lower abdominal and rectal pain.

CASE 6—Mrs. M., aged 44, had a colostomy performed for inoperable carcinoma of the rectosigmoid in April, 1931. Eighteen months later she began to experience pelvic pain which required opiates for relief. Nov. 26, 1932, 1 cc of absolute alcohol was injected through the third lumbar space and repeated five days later. Five months later the patient was still free of pain, required only mild sedatives and no opiates, although the cancer was extending.

PROGNOSIS

The question of prognosis does not enter in the class of cases under discussion as all patients die of the malignant condition or of intercurrent disease. Schreiner and O'Brien⁵ of the New York State Institute for the Study of Malignant Disease reported results in 200 cases of carcinoma of the rectum which were treated by irradiation, but without surgery except colostomy for obstruction, and electrocoagulation for selected cases involving the anal ring and the lower part of the rectum. In the group of patients in whom the growth was limited to the wall of the bowel (radically operable), 17 per cent remained well five or more years. Among patients with malignant infiltration of surrounding tissues and fixation—mechanically inoperable—39 per cent had palliation of from one to four years. The third group with metastases disseminated in the liver and lymph nodes of the mesentery or groin, all died, only a few obtaining any palliation from the treatment.

Individualization is essential in the treatment of advanced carcinoma of the gastro-intestinal tract. The blood picture is an important guide and should be observed at frequent intervals. A low hemoglobin and a white cell count under 6000 preclude roentgen therapy which under these circumstances, tends further to vitiate the blood, unless the balance can be restored by blood transfusions or other measures.

CONCLUSION

Our experience in a rather large group of cases justifies the conclusion that treatment by palliative surgery

irradiation and suitable supportive measures prolongs life in comfort in many patients suffering from advanced malignancy of the gastro-intestinal tract

555 Park Avenue

ABSTRACT OF DISCUSSION

DR GEORGE E BINKLEY, New York. The treatment of advanced gastro-intestinal carcinoma deserves careful consideration. Patients with advanced disease may last for only a few months or may live for four or five years. In most instances their burden can be greatly lessened and life made more pleasant by appropriate treatment. This paper also emphasizes that in the treatment of cancer the object may be either a clinical cure or palliation. Clinical cures are impossible in many cases, owing to the extent of the disease or to the physical condition of the patient. Under these unfavorable circumstances palliation is the method of choice, as it offers more than the most radical methods of treatment. Dr Yeomans has taken up the chief problems, namely, the relief of obstruction, growth restraint or regression of the cancer, and increasing the patient's general physical condition. There is another factor which should not be overlooked, that of keeping up the patient's morale. It is more easily accomplished when the patient is unaware of his pernicious disease. It is a serious mistake to tell a patient that he has advanced cancer and that nothing of value can be accomplished by treatment. Short-circuiting operations for the relief of obstruction are of value and should be employed. The type of operation is largely governed by the location of the tumor, the pathologic changes, and the condition of the patient. Radiation therapy offers many of these patients a high degree of palliation. External irradiation by roentgen rays or radium has the largest field of usefulness. In accessible locations, such as the rectum, interstitial irradiation is often of value. Radiation therapy when properly employed produces a varying degree of growth restraint and decreases infection of the sloughing mass thereby lessening the local and general symptoms. I have not had any experience with the injection of alcohol. The method offers possibilities of relieving low abdominal pain.

DR HARRY H BOWING, Rochester, Minn. My attention has been directed to what can be accomplished through well planned or cautious irradiation. Treatment in advanced cases should be applied with the hope of palliating or reducing as much as possible the existing or potential distressing complications. For example, usually bleeding is effectively controlled. The serosanguineous discharge with the characteristic odor is favorably influenced. The pain has also stopped in many cases. Initial irradiation should be adequate. However, every endeavor must be made to avoid the possible complications of radionecrosis or severe systemic reaction. In many cases, internal disease of the various systems may be of sufficient importance to demand treatment. As a rule surgical therapy for cure is not to be considered in the treatment of advanced cases, and yet it is the most effective method when skilfully applied in selected cases. Palliative surgical therapy or surgery of approach to radium therapy is necessary in some cases. The attitude of despair toward the patient with advanced carcinoma is regrettable. Some responsible party should be instructed regarding the plan of attack and the probable prognosis. To the consideration of cases of carcinoma of the esophagus may I add the technique of dilation is recommended by Drs Plummer and Vinson. I have not employed the method of implantation of gold seeds in the treatment of advanced cases of gastric carcinoma, but the encouraging observations of others will serve as a guide in the future. Polyps in the stomach, colon, sigmoid and rectum demand more consideration. In some cases it seems obvious that the carcinoma bears a direct relationship to the polyp. Evidently whenever possible the polyp or polyps should be removed. Electrosurgery is a valuable adjunct in treating rectal carcinoma in that it controls bleeding and thus facilitates the intratumoral implantation of seeds or needles. It helps to obtain a sterile field and reduces the bulk of the tumor permitting more adequate radium treatment of the base of the malignant neoplasm. Morphine should be withheld as long as possible. As a rule the simple sedatives either alone or in combination with the barbituric acid hypnotics are of

distinct service. Any preparation that possesses pain-relieving properties without the tendency to habit formation should be preferred. Local applications of mild rubefacients, as well as application of warm moist or dry heat to the painful body surface affords much relief. I am deeply interested in the report concerning the subarachnoid injections of absolute alcohol for pain.

DR LOUIS J HIRSCHMAN, Detroit. I will take issue with some of my friend's remarks on the management of advanced cases and I want to say a word about the hopelessly advanced ones. These patients come after a laparotomy and when the liver is hopelessly involved, and the carcinoma of the intestinal tract, particularly of the large bowel, is adherent to large vessels. Surgical therapy here is absolutely out of the question except possibly for the relief of obstruction. I have seen these patients subjected to radiation and particularly to high voltage roentgen therapy, probably as a means of keeping up their morale or as a means of palliation. Patients suffering from carcinoma for any length of time return from the roentgen treatment mentally and physically unhappy, nauseated, depressed and miserable. I ask whether it is fair to subject a patient to a treatment as drastic, uncomfortable, depressing and nauseating as high voltage roentgen therapy, when one knows that it is not going to help him a bit. Some of my friends will say, "We want to make them as comfortable as possible as long as we can," but they withhold morphine till the last minute. How many physicians, if suffering from a hopelessly inoperable carcinoma of the bowel, would not want relief? It doesn't take the patient long to know that his condition is hopeless. Isn't a physician derelict in his duty when he fails to give relief by withholding the sedative or narcotic? If there is any one place in the practice of medicine for the employment of morphine, it is for the poor unfortunate patient who is hopeless and in distress and who cannot hope for more than relief.

DOES QUININE IN THE INDUCTION OF LABOR HAVE A DELETERIOUS EFFECT ON THE FETUS?

E L KING, MD
NEW ORLEANS

Quinine for many years has been credited with oxytocic properties, but there appears to be some difference of opinion as regards its efficiency when so employed. Sollmann¹ states that "moderate doses of quinine stimulate, and high doses depress, the contractions and tone of the uterus, excised and in situ. The stimulant action increases with the excitability of the uterus in the process of pregnancy. Clinically, quinine has little or no effects unless the pains have started. It is therefore ineffective for inducing premature labor." He further states that it is used clinically to stimulate weak labor pains but adds that it is often difficult to prove the clinical response after oral administration because of the slow absorption.

Dodek,² working in the same institution under Sollmann's guidance and employing a new recording apparatus, found that the drug had no effect when administered to two pregnant women at term and caused only feeble and transient pains in the third patient. In established labor he noticed a slight increase in the force of the contractions but no appreciable effect on the course of labor. He thinks that its value has been

overestimated. However, it must be borne in mind that his deductions are based on a small number of cases tested and hence cannot be accepted as final.

Bourne and Burn,³ studying labor pains by means of an intra-uterine bag connected to a recording apparatus, found that quinine when given to a woman in labor "showed very little effect of a kind calculated to hasten delivery." The pains were more frequent but the height of these contractions was less than before. "It is evident that the powerful action of quinine on isolated portions of smooth muscle when suspended in a bath is little guide to its effect on a uterus in labor, and that its action on the parturient human uterus has been much overstressed." They also feel that it has little or no value in the induction of labor and quote the experiments of Rubsamen in corroboration.

Schubel⁴ feels that a sharp distinction must be made between the action of the drug on the isolated but living uterus and the uterus in situ. He found that in cats the intact uterus is caused to contract definitely in from one to two hours by a dosage of from 1 to 2 mg. per kilogram of body weight but that larger doses cause a paralysis. He holds that in women small doses, from 1 to 2 mg. per kilogram of body weight, are to be used and that such doses sensitize the uterus to the action of posterior pituitary.

Williams⁵ states that in secondary uterine inertia the administration of 15 grains (1 Gm.) of quinine sulphate by mouth, or the same amount of the hydrochlorate hypodermically, "is promptly followed by a marked increase in the frequency and efficiency of the uterine contractions," but that, if this amount produces no effect, further administration is useless. He also states⁶ that the result of attempts to induce labor with castor oil and quinine have been very uncertain but that when supplemented with solution of pituitary according to Watson's method, labor developed in the majority of instances. He lost several children when employing this technic and ascribed these fatalities to the pituitary extract, even when given in doses of only 2 to 3 minims (0.1 to 0.2 cc.), as the heart tones disappeared after tetanic contractions had developed. Hofbauer's technic, on the contrary, had no deleterious effect on the child in his experience, so that it would appear that the bad results in the first series could not be charged to the quinine that was administered.

De Lee,⁷ in discussing uterine atony, says that quinine should seldom be employed, as it often causes premature discharge of meconium and annoying postpartum oozing. In induction of labor, he uses castor oil and one 3-grain (0.2 Gm.) dose of quinine, supplemented by other measures.

It thus appears that there is considerable uncertainty, both pharmacologically and clinically, as to the efficacy of quinine as an oxytocic. All observers seem to be agreed that it will not of itself initiate uterine contractions, although Schubel⁴ states that thirteen out of thirty-nine women aborted after quinine therapy alone, the dose varying from 0.5 to 1 Gm. Sollmann⁸ states that abortion has sometimes followed toxic doses, which he ascribes to the general toxicity rather than to direct

uterine action. It is a matter of common knowledge in malarial sections that quinine can be administered in therapeutic doses to pregnant women without the risk of producing abortion or premature labor. As previously stated, the drug is frequently employed to stimulate weak contractions in inertia of the uterus, although the experiments of Dodek and of Bourne and Burn indicate that confidence in its efficacy under these circumstances is not well founded. Sollmann¹ states that when thus used its effect is generally perceptible within forty minutes and that this effect is more persistent than with solution of pituitary and is safer, as there is no danger of producing tetanic contractions. He also affirms that it is often difficult to detect any clinical response after oral administration, owing to the slow absorption. This authority, incidentally, feels that, owing to slow absorption from the rectum, quinine, as used in the Gwathmey method, does not counteract the depressant action of the ether, unless through the effect of local irritation. Mathieu⁸ feels that the quinine can be eliminated from the Watson method with no difference in the results. In the last 120 cases of a series of 320, quinine was not employed, and his results were the same as in the 200 in which it was administered.

What evidence is there to suggest that there may be a possibility of danger to the fetus from quinine administered to the mother? It is a matter of common knowledge that meconium is frequently noted in the amniotic fluid when the membranes are ruptured spontaneously or artificially after the administration of quinine in the medical induction of labor. Dilling and Gemmell⁹ in their first paper, reviewing 765 collected cases of induction in which quinine was used, stated that they did not find any significant difference in the percentage showing meconium in the amniotic fluid, as compared to a control series. However, in their second paper¹⁰ they state that in 100 cases of normal labor meconium was noted at the time of the rupture of the membranes in 8 per cent, while in patients in whom labor was induced by the aid of quinine it was present in 34.6 per cent. They feel that it was probably due to relaxation of the sphincter or to intra-uterine asphyxia rather than to stimulation of the intestinal musculature of the fetus. Meconium was present more often after quinine alone than after quinine plus solution of pituitary. These observers made elaborate quantitative and qualitative analyses of the maternal blood and urine, the amniotic fluid, the fetal urine and tissues of still-born children, in order to determine the presence and concentration of quinine following its administration to the mother. They found the highest concentration of quinine in the maternal tissues six or eight hours after the first dose. It was found in the amniotic fluid from nine to eleven hours after administration, and in the urine of the fetus from six to twelve hours after the last dose was administered to the mother. They feel that quinine in a concentration of 1 to 100,000 or over in the maternal or fetal blood cannot be regarded as devoid of risk to the fetus. In

order to obtain a sufficient concentration in the maternal blood to affect the uterus, they feel that three 10 grain (0.65 Gm.) doses at hourly intervals are requisite. They state that concentrations of quinine which may be toxic to the fetal tissues may persist in the fetus many hours after the wave of secretion in the maternal urine has subsided. This is probably due either to the slow return of the quinine from the fetus to the mother or to inability of the fetal kidneys to excrete concentrations over 1 to 6 000. It is to be noted that quinine, when used in the induction of labor, is given at much shorter intervals than when used in the treatment of malaria, and the lack of deleterious effect under the latter circumstances must be due to the lower concentration in the maternal blood because of the longer spacing of intervals between the doses.

The first instance of fetal death ascribed to the administration of quinine to the mother in the induction of labor was reported by Gellhorn¹¹ in 1927. His patient received 2 ounces (60 cc.) of castor oil at 7 a. m. and 10 grains (0.65 Gm.) of quinine sulphate at 9 and 11 a. m. and 1 p. m. No labor pains developed. Toward evening all fetal movements ceased, and no fetal heart tones could be detected after this time. The usual signs and symptoms of fetal death manifested themselves. Fifteen days later, mild pains developed which were intensified by the use of a Voorhees bag. A macerated child was delivered. Examination of the placenta and autopsy of the child revealed nothing to account for the fetal death. The Wassermann reaction was negative and there was no evidence of fetal or maternal syphilis. A similar case was reported verbally to Gellhorn by J. L. Baer and also one by F. W. Lynch. In the latter instance castor oil, followed by two 10 grain doses of quinine, was administered and was repeated in three days and again two days later. Labor did not develop. Eight days after the last dose the patient reported that no fetal movements could be felt and no fetal heart tones could be elicited. She subsequently delivered a still-born child.

Torland¹² reported the case of a woman with a previously unknown idiosyncrasy to quinine who developed dyspnea, urticaria, and a mottled purplish red skin eruption two hours after administration of 10 grains of quinine sulphate following the castor oil as in the Watson method. Shortly after the quinine was given, strong fetal movements were felt which then ceased. No fetal heart tones could be detected (there was no note as to the time they were last heard before the treatment was commenced). Satisfactory labor developed and she was delivered ten hours after the administration of the quinine by the aid of an easy low forceps operation. Autopsy of the baby showed blood in both pleural sacs, the pericardium and the peritoneum, also an acute nephritis. Dilling and Gemmell⁹ in their first paper reviewed 765 collected cases of medical induction and of the forty-six stillbirths in this series they feel that eight (including those reported by Gellhorn and Torland) were probably due to the quinine. In these instances the heart tones ceased within thirty-six hours of the administration of the quinine and before the onset of labor. In their second paper¹⁰ they analyzed twenty-six cases of fetal death following medical induction including the use of quinine. In seven instances the only plausible explanation

is that death was due to the quinine. Five deaths are listed as doubtful, and the other fatalities were definitely ascribed to other causes. In the whole series reviewed, the positive and doubtful cases constitute 13.6 per cent of the total number of babies delivered. In a control series, no cause for the fetal death could be found in 13.4 per cent of the total number of babies. As these rates are so nearly identical, they conclude that, although there is scientific evidence available indicating that there is a risk to the child when labor is induced by the aid of quinine, from a practical point of view this risk is so small that a labor so induced is at least as safe as an unassisted delivery. In line with this view, Guttmacher and Douglas,¹³ in reporting 120 inductions according to Slemmons' method of using castor oil and quinine followed by rupture of the membranes, report that none of the seven fetal deaths can be ascribed to the induction of labor.

I have observed three instances in my service at Charity Hospital in each of which it appears logical to conclude that the quinine was responsible for the fetal death. A brief report of these cases follows.

REPORT OF CASES

CASE 1—In a primipara in her early twenties, labor was induced because she was a few days past term. One ounce (30 cc.) of castor oil was given at 6 p. m. followed by an enema at 7 p. m. Ten grains of quinine sulphate was given at 8 o'clock and was repeated at 10 and 12 p. m. Labor pains developed about 1 a. m. and the cervix was fully dilated at 5 o'clock. The membranes were ruptured artificially at this time by the intern, and the amniotic fluid was found to be deeply stained with meconium. Unfortunately, no attempt to hear the fetal heart tones was made. The second stage progressed satisfactorily, and the head reached the perineum shortly after 6 a. m. As there was some slowing of the pains at this time, 0.5 cc. of solution of pituitary was given, apparently on insufficient indications. Satisfactory but not over-strong pains developed and a still born baby was delivered at 6:30. There was no anomaly of the cord or placenta and no evidence of premature separation of the placenta. The patient was definitely not syphilitic and autopsy on the child disposed of no lesions except petechial hemorrhages in the brain, suggesting asphyxia. I feel that this death can be ascribed to the quinine and not to the solution of pituitary as the pains after the latter drug was given were not violent, the uterine contractions did not become tetanic and autopsy did not disclose any evidence of intracranial hemorrhage or other injury.

CASE 2—Induction was attempted in a multipara because of undue prolongation of pregnancy. The full treatment with castor oil, quinine and solution of pituitary was employed according to Watson's method three 10 grain doses of quinine being used but with 0.25 instead of 0.5 cc. doses of solution of pituitary. No labor pains developed but in the afternoon about sixteen hours after the last dose of quinine the patient reported that fetal movements had ceased. Careful and repeated auscultation failed to elicit the heart tones. A few days later spontaneous labor developed and a macerated fetus was delivered. As in the first case nothing could be found to account for the death of the child and the evidence appears very conclusive that the quinine was the agent responsible for the fatality.

CASE 3—In a young primipara whose pregnancy had advanced a few days past the expected date of delivery labor was induced as outlined in case 2. Satisfactory pains developed and the patient delivered spontaneously after an easy labor. The fetal heart tones disappeared early in the first stage. Labor pains were normal throughout and at no time were they unduly severe. Autopsy disclosed nothing to account for this fatality. Qualitative chemical tests by Dr. Emmerich von Harrn of the Department of Pathology of the Charity Hospital disclosed the presence of an appreciable amount of quinine in the brain.

¹¹ Gellhorn, George. Can Quinine Kill the Fetus in Utero? *Am. J. Obst. & Gynec.* 13:9 (June) 1927.

¹² Torland, Torleif. Fetal Mortality After Induction of Labor by Castor Oil and Quinine. *J. A. M. A.* 80: 1190 (April 14) 1925.

¹³ Guttmacher, A. F. and Douglas, J. C. Induction of Labor by Artificial Rupture of the Membranes. *Am. J. Obst. & Gynec.* 21:45 (April) 1931.

tissue. In the light of the experimental work of Dilling and Gemmell, it appears logical to ascribe this death to the quinine used in the induction.

CONCLUSION

It appears that one cannot ascribe to quinine a role of any particular importance in the induction of labor. It is certain that it has no such action when employed alone, and it is questionable whether it is of any value when used in conjunction with other drugs or procedures as in Watson's and Slemons' methods. In view of the reported fetal deaths, which can in all fairness be charged to the quinine used, it would seem to be wise to discontinue entirely the use of this drug in the induction of labor or at least to employ it in smaller doses. There seems to be little doubt that equally good results will be obtained without subjecting the child to the added risk of poisoning from the quinine employed.

931 Canal Street

ABSTRACT OF DISCUSSION

DR F. H. FALLS, Chicago. Quinine ordinarily is not a very toxic drug. Adults can take large doses of it, and there are on record cases in which as much as 600 grains (39 Gm.) has been given an adult in twenty-four hours without any deleterious effect. One would therefore suspect that in the doses ordinarily given for the induction of labor, namely of three 10 grain (0.65 Gm.) doses there would not be any danger to the fetus. However, when quinine is given, some of these babies die suddenly. The height of the concentration of the quinine in the maternal blood after administration occurs in about five or six hours and therefore it would seem that deaths occurring as late as sixteen and twenty-four hours after the administration could not reasonably be ascribed to the drug. The fact that small doses stimulate uterine contraction and larger doses tend to inhibit contraction is a strong argument for the use of small doses. I analyzed 100 cases of induction of labor by the use of a modified Watson method and found that in these 100 cases the fetal mortality was 10 per cent uncorrected. Then I analyzed a thousand cases in which the labors had started spontaneously. The mortality was 58 per cent uncorrected. At first glance it would seem that the quinine was responsible for an increase of about 4 per cent but in those cases in which quinine had been given twenty-five out of the hundred were cases of toxemia, and of the other seventy-five there were many in which serious pathologic conditions were present, such as postmaturity, poorly compensated heart cases and diabetes. Therefore the evidence that quinine is detrimental to the fetus is not convincing. I am convinced that quinine during labor is dangerous or may be dangerous. I think that it is possibly due to an idiosyncrasy of certain women to quinine. I have seen stormy pains in within fifteen minutes after the oral administration of 10 grains of quinine so stormy that the women had to be given an anesthetic and the baby delivered by forceps in order to prevent a serious asphyxia. In the cases in which death occurred in Dr. King's series solution of pituitary was given and might have been responsible as well as quinine. I agree with Dr. King that in the induction of labor smaller doses of quinine are to be used instead of the 10 grain doses advocated by Watson.

DR EDWARD L. KING, New Orleans. Dr. Falls mentioned the late death of these children as an argument against quinine as the cause. It was brought out by Dilling and Gemmell that the quinine remained in the fetal tissues long after the crest of the quinine wave had passed in the maternal blood stream. It seemed to be retained longer by the fetal tissues once it got there. Another point to be remembered is that the death may be reported to the physician several hours after it has actually occurred. The woman notices that the fetal movements have stopped but she may not report the fact until she is absolutely certain of it. As Dr. Falls stated, the percentage of deaths in his quinine series was higher because of complications. That of course did not concern the three babies that I reported, because there were no complications, no toxemia and no instru-

mentation. I do not think that the fact that these patients had received solution of pituitary can be brought into consideration. In one instance the solution of pituitary was given only a few minutes before the baby was born and there was no evidence at autopsy of any intracranial or other injury. In the second instance there were no labor pains whatever following the administration of the Watson method, including the solution of pituitary, and in the third case again the labor pains were normal and not overstrong, and there was not at autopsy anything to show any intracranial or other damage to the fetus. I think that it is rather clear that the death of these babies can be charged to the quinine, at least the matter deserves consideration and should make one consider very seriously the question of using quinine at all, or at least the advisability of reducing the dosage in the induction of labor.

TULAREMIC PNEUMONIA

REPORT OF A CASE

JAMES R. GUDGER, M.D.

DFTROIT

In recent years, tularemia has taken a place of major importance among the acute infectious diseases. The extremely infectious nature of the organism *Bacterium tularensis*, and the various types of the disease in man, are of prime importance to the clinician. An increasing dissemination among the lower animals has been the subject of much investigation. Study of the extensive literature reveals that in certain cases of the typhoid type the lesions are most prominent in the lungs. Pulmonary complications are often diagnosed with difficulty and are attended by a grave prognosis. Two cases of tularemic pneumonia have been reported, in one of which the patient recovered. It is my purpose in this paper to report an additional case of tularemic pneumonia that terminated fatally.

REPORT OF CASE

Severe generalized infection, greatest degree of involvement in the lungs without lymphatic enlargement, diagnosed by serum agglutination, course lasting thirty-one days.

History.—T. P., a white man, aged 32, admitted, Nov. 12, 1932, complained of chills, fever, profuse sweating and prostration. The onset had been sudden, ten days before, with a severe chill, aching and perspiration. The next two days he experienced some muscular pains in his back and legs, these subsided and he was practically free from symptoms for one day. The chills and sweats continued with frequent attacks of coughing, producing a small amount of thick blood streaked sputum on the day before admission. There was no nausea or vomiting. A communication from a relative received six days after his admission reported a cut on her finger from a bone while cleaning rabbits. She was taken with chills, fever, sweating and axillary adenitis on the same day the patient became ill. The cut soon became an ulceration which healed with difficulty three or four weeks later. The patient admitted having cut his left thumb on a piece of bone while cleaning rabbits with his relative on October 27. The cut healed promptly and he continued to hunt and dress rabbits near Jackson Mich. There was no history of exposure to typhoid or alcaligenes infection. He had pneumonia in childhood, pneumonia and pleurisy in 1909, and influenza, pneumonia and pleurisy in 1918.

Examination.—The patient was alert and cooperative, the most important observations being fever of 103.4 F., pulse rate of 84 and respirations 24. The face was flushed, the mucous membranes of the nasopharynx were injected and the tongue was heavily coated. There were a few shotty glands in the left cervical area but no other lymphadenopathy. The chest

From the Department of Medicine, Henry Ford Hospital.

was normal to percussion, no rales were heard. The heart sounds were normal, the rate was regular, and there were no murmurs. The blood pressure was 105 systolic, 60 diastolic. Abdominal examination revealed slight tenderness along the right costal margin, the liver and spleen were not palpable, and there was no distention. Knee-kick reflexes could not be obtained. The blood count on admission was entirely normal. The urine contained a trace of albumin and sugar. The results were negative in other laboratory studies, including a blood Wassermann test, blood culture, Mantoux test, intradermal test with 0.1 cc of brucellin, serum agglutination for *Alcaligenes abortus*, and smears of the sputum for acid fast organisms. The Widal test was positive for *Salmonella schottmulleri* (*Bacillus paratyphosus* B) in a titer of 1:40. Roentgenograms of the chest revealed a rounded shadow of increased density extending outward from the region of the left hilus.

On the day of admission the patient had a severe chill accompanied by profuse perspiration. His toxic state gradually became more severe and two days later signs of the pneumonic process were well developed. There was impairment in the left interscapular space, with many crepitant rales. The leukocyte count at this time was normal but the polymorphonuclear count was 80 per cent. The temperature varied between 103 and 104 F, with a pulse rate of 84 to 96 per minute. Agglutination of the patient's serum with *Bacterium tularensis* in a titer of 1:320, on the sixteenth day of his illness, established the diagnosis. Four hundred cubic centimeters of convalescent blood with an agglutination titer of 1:1,280 was given, without improvement. Several small red maculopapular spots, characteristic of the skin manifestations, were seen over the chest and abdomen. There was no lymphadenopathy, however, at any time. The slow pulse rate became more rapid as prostration increased, and the slowly spreading process involved the right side of the chest. The patient was irrational and incontinent of urine and feces. He continued to cough up small quantities of very thick greenish-gray sputum. Signs of consolidation were evident over the left lower lobe, but on the right there was only moderate impairment in the presence of many coarse rales. On the twentieth day 12 cc of antiserum¹ was given intravenously. This was repeated on the twenty-fourth day, with only slight or temporary improvement after each dose. Toward the end of the third week there was a rapid rise in the agglutination titer for *Bacterium tularensis*, finally increasing to 1:5,600. Though definite signs of meningitis were not evident, the lethargic state and occasional muscular twitching suggested involvement of the central nervous system. Spinal puncture yielded normal cerebrospinal fluid which did not agglutinate *Bacterium tularensis* and the culture of which was negative. One hundred cubic centimeters of bloody fluid was aspirated from the left pleural space. *Bacterium tularensis* was obtained in pure culture from this fluid. Late in the course the leukocyte count was 4,800, with 77 per cent polymorphonuclears, 3 per cent small lymphocytes, 15 per cent large lymphocytes, 3 per cent monocytes and 2 per cent eosinophils. The rise in serum agglutination for *Bacterium tularensis* was accompanied by a positive Widal reaction, the maximum agglutination titer reaching 1:640. The phagocytic indexes for *Bacterium tularensis* and *Alcaligenes abortus* showed a steady increase until they reached 100 per cent during the last few days before the patient died. Convalescent serum was given intramuscularly without improvement. Because of respiratory embarrassment and cyanosis an oxygen tent was used without apparent effect on the rapidly fatal course. The patient died December 2.

Appearance of chest on tenth day of illness showing pneumonic process on left

Necropsy—Nothing unusual was noted in the external examination of the body. The left pleural cavity contained 800 cc of bloody turbid fluid. The surface of the visceral pleurae was covered by a thick, fibrinopurulent exudate, most abundant over the lower lobe. This lobe was completely consolidated and a small area of consolidation was seen near the apex in the upper lobe. When sectioned, the tissues of the lower lobe appeared grayish red, with many small areas of a peculiar grayish blue scattered diffusely throughout. These were granular, necrotic, and unrelated to the bronchi. On the right side there were a few adhesions but there was no fluid. The middle and lower lobes were greatly congested. Scattered throughout the upper lobe were small areas of consolidation, which, when sectioned, had a translucent dark red appearance. These were similar to the area in the right upper lobe. The large bronchi on both sides were filled with tenacious mucopurulent material. The peribronchial and retroperitoneal lymph nodes were enlarged but not grossly caseous. The liver and spleen were congested, but no areas of infiltration or necrosis were seen. The other organs, including the brain and meninges, were normal except for some congestion.

Sections from the consolidation in the lungs showed various degrees of a severe acute inflammatory process. In the lighter pink areas the bronchi contained considerable exudate. The blood vessels were dilated and engorged. Many of the alveoli were filled with disintegrating polymorphonuclear leukocytes and necrotic material. In the darker areas there were foci of more advanced necrosis in which the alveolar walls could not be made out or appeared to fuse with the necrotic content. In other areas the lining cells of the alveoli appeared swollen and unusually distinct. In a few places, giant cells were seen around the foci of necrosis. The peribronchial lymph nodes showed irregular areas of necrosis without adjacent infiltration. Many large pigment cells were seen in these and also in the mesenteric and retroperitoneal glands. Tissue sections from various organs of the body stained for *Bacterium tularensis* failed to demonstrate the organism. Two rabbits inoculated with a saline suspension of splenic tissue died on the third day with the characteristic lesions. Positive cultures for *Bacterium tularensis* were obtained from the spleen and from the blood of the heart.

COMMENT

Fourteen fatal cases of tularemia with postmortem observations have been reported. In one of these cases the chest was not prosected. Of the others 92.3 per cent (twelve out of thirteen) showed intrathoracic lesions of tularemia, 61.5 per cent (eight out of thirteen) showed definite inflammatory processes of pneumonia. Permar and Machchlan,² in a study of seven cases in which the chest was prosected, state that 87.5 per cent showed tularemia lesions of some kind in the lungs, 62.5 per cent showed a diffuse pneumonia, and thirty-six per cent of fatal cases showed pneumonia clinically or at postmortem. In a case reported with the postmortem observations they noted the absence of lymphadenopathy.

Other cases showing more or less extensive lung involvement reported with the necropsy include the case by Verbricke³ in 1924. Inundice was noted as a

1 The supply of antiserum was furnished by Dr. Lee Fosha.

rare complication in this case Francis and Callender,⁴ and Bunker and Smith⁵ mentioned pathologic features of special interest in their cases Palmer and Hansmann⁶ called attention to the absence of any clinical symptoms of a complicating bronchopneumonia in a case reported by them In the review of a rapidly fatal case, Simpson⁷ suggested that in many cases tularemic areas in the lungs are erroneously reported as bronchopneumonia Massee⁸ described a case of tularemia of the typhoid type in which the red hepatization at the bases appeared as a "bronchopneumonia of the confluent type"

In a discussion of the pulmonary lesions, Blackford⁹ in May, 1932, stated that "at this time the criteria for making the diagnosis of tularemia of the lung from pathologic studies alone seem indefinite further work along this line is necessary" He reported a case of acute tularemia with extensive intrathoracic lesions, calling attention to the frequency with which the disease attacks the lung Among the conditions found in both tularemia and tuberculosis of the lung, the author mentioned pleural effusion, bronchopneumonia, cavitation and abscess formation Others¹⁰ have also published necropsy results with descriptions of the characteristic lesions The areas of focal necrosis have a marked resemblance to caseous tubercles

In 1931, Reimann and Rose¹¹ pointed out the similarity between the granulomatous infection, classed as pseudotuberculosis in Europe, and the typhoid type of tularemia Some authors describe the mononuclear reaction as characteristic of early tularemic lesions, and the appearance of polymorphonuclear leukocytes as a secondary reaction In one case Simpson mentions the absence of any evidence of endothelial proliferation or thrombosis of the small blood vessels, in the lymph node and splenic lesions, as have been reported by others There is considerable variation in the leukocyte count reported with cases of severe or widespread infection The majority show a moderate degree of leukocytosis with an increase in the polymorphonuclear cells, but a normal count, or even leukopenia, may exist Serum agglutination is present the second week and rapidly increases during the third

Various authors estimate the mortality in all cases of tularemia to be about 4 per cent However, Simpson

states that in his local ty, Dayton, Ohio, tularemia is believed to cause death in approximately 11 per cent of cases Tureen¹² has reported a case of tularemic pneumonia with recovery This is remarkable in that the overwhelming toxemia associated with pulmonary lesions, especially a pneumonic process, is often fatal An ulceration at the site of infection with an associated lymphadenopathy of the regional nodes, is characteristic of the average case of tularemia Dissemination of infection is thought to be chiefly through the lymphatics Goodpasture and House mentioned the possible encroachment on blood vessels by the necrotizing foci and subsequent blood stream infection Laboratory workers have become infected through the unbroken skin and it is not surprising that of three fatal cases, in which lesions within the chest were most marked, none presented definite cutaneous ulcerations In two of these, absence of gland enlargement was noted These observations point out the necessity for further investigation of the pathologic processes in tularemia

SUMMARY

1 In a fatal case diagnosed as tularemia, the clinical observations and necropsy gave evidence of extensive pneumonia believed to be tularemic

2 The exact route by which the infection reached the lungs, whether through the blood stream, lymphatic channels, or the respiratory passages, is unknown

3 In the terminal stage the infection was generalized, and there was clinical evidence of extreme toxicity

4 Lesions characteristic of those produced by tularemia were present in the lungs and peribronchial lymph nodes

Clinical Notes, Suggestions and New Instruments

BILATERAL ABDUCTOR PARALYSIS IN A TWO DAYS OLD INFANT, WITH TRACHEOTOMY AND RECOVERY

SAMUEL J PEARLMAN, M D AND NORMAN LESHIN, M D
CHICAGO

A case of bilateral abductor paralysis in a 2 days old infant requiring tracheotomy and ending in recovery is being reported to place on record one of the youngest infants recovering after a tracheotomy It is also one of the very few cases reported in the literature of bilateral abductor paralysis in an infant, so diagnosed by direct laryngoscopic examination

Adams¹ reported the case of a 10 months old infant with attacks of crowing inspiration and dyspnea since birth Laryngoscopic examination showed the vocal cords immobile in the adductor position not inflamed, with an infolded epiglottis The softer structures of the larynx including the false cords tended to roll in over the cords during inspiration Tracheotomy was done with relief of the symptoms, but the patient succumbed to a sepsis ten days later Tucker² reported a case of a 2½ months old infant with urgent dyspnea Direct laryngoscopic examination showed a bilateral posticus paralysis with an anteroposterior tracheal compression Roentgen examination revealed a widening of the mediastinal shadow with evidence of anteroposterior tracheal compression Tracheotomy and roentgen therapy for the thymus gave complete relief and

subsequent recovery. Jackson³ states that he has seen three cases of laryngeal stenosis due to perichondritis in infants a few weeks old. The laryngeal stenosis was revealed by laryngoscopic examination, and the symptoms were immediately relieved after tracheotomy with subsequent recovery and cure. These cases were all forceps deliveries and traumatism may have been the etiologic factor. The stenotic symptoms began between the second and fourth weeks. Jackson⁴ reported one case in detail in which obstructive symptoms began three weeks after delivery in an infant 8 weeks old. The child was moribund from loss of sleep and starvation. The left side of the subglottic region bulged inward until there was only a slight crevice through which to breathe. The swelling was firmer than edema and contained pus. A tracheotomy was done and considerable mucopus escaped from the trachea as soon as the tracheal incision was made. There was immediate complete relief of the dyspnea following the tracheotomy with subsequent recovery. These cases of laryngeal stenosis in the new-born are not common compared to the number of births, according to Jackson, but are usually overlooked when they do occur.

REPORT OF CASE

M. M., a baby girl, aged 2 days, was admitted to the pediatric service of the Michael Reese Hospital with a history of dyspnea and some cyanosis since birth. Delivery was normal; no instruments were required; the baby had good color and weighed 10 pounds (4,536 Gm). The child had been restless and crying most of the time since birth. On the second day she became blue with frequent attacks of marked dyspnea every ten minutes, lasting about five minutes. The family history was negative, five other children were living and well.

On admission the baby was well developed, the temperature was 96.4 F, the pulse, 186, and the respiration rate, 56. There was difficulty in breathing with marked inspiratory stridor, retraction of the costal margins and cyanosis of the lips, face and hands. The baby was lying quiet and listless. There was an apparent fulness of the neck with a palpable, soft cystic mass definitely circumscribed over the trachea, extending down to the clavicle on the right side. There was also bulging and dullness over the entire sternum. There were no palpable masses in the pharynx. Roentgen examination of the chest after admission revealed a tremendously enlarged heart with a very broad mediastinum. A congenital heart condition plus a persistent thymus was considered. Because of the marked dyspnea, a low tracheotomy was done under local anesthesia by one of us (S. J. P.). The thyroid gland was found to be much larger than usual, engorged and soft. The condition of the infant was immediately greatly improved.

Three days after admission, examination by Abraham Levinson, attending staff pediatrician, revealed a suggestive slight cyanosis, with the heart dullness greatly increased in area. There was mediastinal dullness at the level of the second intercostal space with a bulging of the whole chest, possibly more marked over the precordial area. The heart tones were audible over the entire precordium, loud and rapid, but with no murmurs. The lungs were normal. Roentgen examination of the chest five days after admission showed almost complete clouding of the left lung field produced by a large cardiac shadow. There was also a broad superior mediastinum. A pathologic heart as well as a persistent thymus was considered, with the possibility of an atelectasis of the upper lobe of the left lung.

On the ninth day after admission, the condition of the infant now permitting a direct laryngoscopic examination was done and a bilateral abductor paralysis of the vocal cords was found. The cords were in the midline, pale, with no evidence of any inflammation. There was no swelling or any edema about the larynx. A week later roentgenograms of the chest were negative for congenital heart disease. During the period following the tracheotomy the general condition of the infant remained good except for an occasional attack of cyanosis and dyspnea, which was relieved immediately by cleansing of the tracheotomy tube. Examination by Dr. Levinson now showed the heart border very much smaller. In view of the fact that the heart had become much smaller it became clear that the original pathologic condition had been in the larynx and that the enlargement of the heart was due to a secondary dilatation

which had subsided following relief of the dyspnea by tracheotomy. A month after admission the heart outline was normal. The subsequent course was uneventful except for occasional attacks of slight dyspnea, fever and suspicious lung changes. These were relieved with the removal and cleansing of the tracheotomy tube. Nine weeks after admission, the tracheotomy tube was removed permanently. Another roentgenogram taken at this time revealed a persistent thymus and normal heart borders. The direct laryngoscopic examination now showed the vocal cords to be normal and moving freely. The patient was discharged a few days later, a little over ten weeks after admission, the tracheotomy wound was completely closed and the heart tones were normal. The patient now weighed 10 pounds 3 ounces (4,648 Gm). Examination in the outpatient department two months later showed her to be in good condition, breathing normally and weighing 13 pounds 4 ounces (6,045 Gm).

SUMMARY

1. A 2 days old infant with a bilateral abductor paralysis of the vocal cords required tracheotomy, there was subsequent recovery.

2. Jackson's statement that there is no contraindication to tracheotomy if the indications are well established holds true in this particular instance. The age of the patient might tempt the cautious physician to fear surgical intervention. Caution, however, in this instance meant an almost certain death from asphyxia.

3. The attacks of fever and lung changes were in all probability due to dried secretions in the bronchial tract. The necessary postoperative care of the tracheotomy tube, frequent use of suction with removal of crusts, and good nursing attention, combined to aid in the recovery.

180 North Michigan Avenue.

Special Article

REPORT OF COMMITTEE ON LYE
LEGISLATION

Your committee begs to report that eleven judgments have been entered against different firms and corporations for the misbranding of caustic preparations as provided in the Federal Caustic Poison Act. All of these preparations contain caustic or corrosive substances in packages suitable for household use, and all were found under conditions involving interstate transportation.

1. *Go-Drain*, sodium hydroxide, word "Poison" in type smaller than size required, no complete directions for treatment in case of accidental injury. Consigned by Goulard and Olena, Inc., New York. Transported from New Jersey into Pennsylvania.

2. *"Drain Aid"* George H. Garnet Co., Waltham Supply Co. Not labeled "Poison" and no directions for treatment. Shipped from Pennsylvania into Massachusetts and New York.

3. *Go-Infecto No. 1*, Goulard and Olena, Inc. No word "Poison" no common name of article and no directions for treatment on label. Shipped from New Jersey into Connecticut.

4. *Cold Water Drain Pipe Solvent*, Hercules Chemical Co. New York. Shipped from New York into Colorado. No label giving common name, no word "Poison" and no directions for treatment.

5. *H T H*, Mattheson Alkali Works, Inc. Shipped from New York into Maryland. Not labeled "Poison" and no directions for treatment.

6. *Druso Caustic Pencils* Go ham Aseptic Laboratories, New York. Shipped from New York to Philadelphia. The antitoxin and the printing of the word "Poison" were not in conformity with the provisions of the act. Label implied that the product was manufactured by the Philadelphia Wholesale Drug Co. whereas that concern was not the actual manufacturer.

³ Jackson, Chevalier. *Personal Endoscopy and Laryngeal Surgery*. Laryngoscope Company, 1915, pp. 552 to 553.

⁴ Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 12, 1933.

7 "Hydro Clean", William Harris Plunkett (Plunkett Chemical Co.) The word "Poison," the common name of the article and directions for treatment were omitted from the label. Shipped from Illinois to Ohio.

8 Carbolic acid misbranded, McKesson-Langley-Michaels Co., Ltd. The word "Poison" and the directions for treatment did not comply with the requirements of the Federal Caustic Poison Act. Shipped from California to Texas.

9 Ma Burns' Liniment" containing free ammonia in proportion greater than 5 per cent. Word "Poison," directions for treatment and common name for the caustic substance omitted from the label. Eight dozen bottles of "Ma Burns' Liniment" were shipped by the Ma Burns Liniment Co., Boston, to New Jersey.

10 Biz", Henderson and Skipworth, containing carbolic acid in excess of 5 per cent. Common name the word "Poison" and directions for treatment in case of accidental injury omitted from the label. Shipped from California to state of Washington.

11 Miller's Anti Mole' containing nitric acid in proportion of 68.08 per cent. The common name, the word "Poison" and the directions for treatment were not printed on the label. Shipped by Miller Manufacturing Co. from Nebraska to Missouri.

Each of the caustics found was of potential danger to children and others were dangerous because there was no proper warning on the label.

Your committee has great satisfaction in reporting the foregoing judgments. We took no part whatever in the actions against these violators of the law. All credit is due to the energetic fulfillment of duty on the part of the Food and Drug Administration of the United States Department of Agriculture. Our satisfaction arises because of the full vindication of the action of the Section on Laryngology in the appointment of this committee and of the committee's work since the appointment. It was alleged in many quarters that there was no necessity for legislation as it was imagined by some persons that the manufacturers of caustics would voluntarily comply with the dictates of humanity in labeling caustic substances so as properly to protect the public. It is clear from the foregoing list of violations that there are packers who do not realize the necessity for proper labeling.

Your committee wishes to point out that the foregoing convictions concern the violations in interstate traffic. There are many misbrandings in interstate commerce. It is our duty to obtain adequate legislation in the twenty-four states that are still without such a law and we ask to be continued until this shall have been accomplished.

Your committee requests that its chairman be authorized to send a letter to the Food and Drug Administration of the United States Department of Agriculture expressing the appreciation of this section of the American Medical Association for the efficient way in which action has been taken against violators of the Federal Caustic Poison Act, our interest being only to protect children, so far as possible, from the swallowing of caustic substances.

Respectfully submitted CHEVALIER JACKSON, Chairman

A Real Knowledge of Disease—However greatly medicine was indebted to Virchow and the other noted morphologists for their systematizing of disease and establishing clear understandings of the anatomical basis of many conditions it must be recognized that time has brought about great advances in entirely new directions. The contributions of chemistry and physiology in particular have established viewpoints of the dynamics of many diseases that render the older static or morphological conceptions largely lifeless. The complicated and widely distributed manifestations and effects of certain general diseases and infections push into the background of relative unimportance the limited pathological lesions that may perhaps with justification be regarded as representing the primary foci or seats of onset. A real knowledge of disease requires an understanding of the complexities of the mechanisms of adjustment that follow an initial fault and not infrequently the struggle for compensations occasions new clinical pictures that show little evidence of relation to the primary lesion which thus becomes dwarfed by contrast—Stengel, Alfred. *The Internist as His Own Psychiatrist*. *Ann Int Med* 7:281 (Sept.) 1933.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

ANITA NOSE APPLIANCES NOT ACCEPTABLE

The Anita Company, formerly the Anita Institute now located at 617 Central Avenue, East Orange, N. J., submitted to the Council three appliances for consideration one termed the Modified Splint, the second the Clinical Dressing and Dilator and the third the Anita Nose Adjuster (Anita Nose Brace). All these devices are similar in make up and appearance. They are constructed of porous fabric, one or more inner layers of which are stiffened by processing. The body is designed to cover the external nose and is provided with openings at the apertures of the nares for breathing. Bound and covered wires form the periphery making it semirigid although flexible. Tapes are attached to hold the device on the wearer's head. At an earlier date, an appliance known as the Anita Nose Adjuster (Anita Nose Brace) was submitted but after an investigation by the Council it was declared unacceptable. In accordance with the regular procedure of the Council the report was presented to the firm for thirty days' consideration. The manufacturer requested that the publication of the former report be withheld until such time as new evidence should have been forwarded and considered. This request was granted.

The Anita Company now makes the following physical and therapeutic claims for the appliances:

- 1 The appliance is useful as an external splint for immobilizing the bones and cartilages of the nose after fracture reduction.
- 2 It is useful for the retention of dressings applied to external wounds resulting from accidental injuries and surgical operations involving the external portions of the nose.
- 3 It is useful as a supporter to relieve the strain on sutures such as is employed following resection of the columella etc.
- 4 In plastic surgery the appliances may be used:
 - A For the immobilization of transplants (and grafts) pending natural anchorage.
 - B As a constrictor for inhibiting excessive nasal post operative oedema.
 - C For the application of lateral pressure on the nasal processes of the superior maxillae (and nasal bones) following thinning operations such as that incident to the surgical removal of prominences in hump nose therapy.
- 5 The appliance is useful in non-surgical correction of certain mild deformities of the external soft tissues of the nose in cases where no pathology or bony abnormalities are present such as:
 - A In bulbous noses true atrophy (I) of alar fibro fatty tissues may be induced by the application of gentle pressure (II) over an extended period of time.
 - B In noses with drooping tips due to muscular elongation support is given to the nose tip permitting contraction and strengthening of the Nasalis and Dilatores Naris Anterior and Posterior. The strengthening of Dilator muscles often results in facilitated breathing through the improvement or restoration of their function of resisting atmospheric pressure and keeping the nares open during inhalation (III).
 - C In certain cases of external deviations the appliance may be used for the application of corrective lateral pressure or traction similar to the methods of Josephs, Kenzendorf and Loebell (IV).
 - D In mild cases of retrousse (turned up) noses correction may be accomplished through the simple application of downward traction and pressure (V).
 - E In certain types of flat and low bridged noses improvement may be obtained by slightly squeezing the nares and integument so as to build out the nose anteriorly.

The appliances were investigated by the Council and the correspondence submitted for evidence as to the therapeutic efficacy was given careful consideration. The physical and therapeutic claims for the usefulness of these appliances as an external splint for immobilizing the bones and cartilages of the nose after fracture reduction are not disputed. There is a possibility of the use of such a device, but it is highly probable that most surgeons will rely on complete or as complete as possible reduction and will not use external dressing, rarely will intranasal dressing be used in such cases.

That the appliances are useful for the retention of dressings applied to external wounds is questioned. External wounds properly sutured are quite universally left undressed by the

surgeon, as they heal more quickly and do not make a soppy dressing over the face, which is disagreeable to the patient. Such a dressing could not relieve the strain of sutures with any degree of success.

In plastic surgery the dressing in question might be used for immobilization of full thickness grafts applied on the skin, but usually the surgeon prefers to mold his own from dental wax or use a piece of highly compressible rubber sponge. Flap grafts turned down from the scalp need no retention dressing of any kind, as they are held by sutures.

The Council did not observe that the appliance could in any way inhibit postoperative nasal edema without acting untowardly.

After operations for thinning the nose, no pressure would be indicated or needed laterally on the nasal process.

The Council declares that the appliances cannot be used successfully to correct deformities such as bulbous nose. There is no method except excision for the correction of such cases that gives happy results. The same is said of drooping tip noses and external deviation. Such an appliance could in no way increase the volume or ease of nasal breathing and respiration during inhalation. Practically all natural and acquired deformities must be treated by surgical means and any loosely applied apparatus attempting to make corrections by pressure, no matter how long applied, would fail to affect the underlying cartilage or bone, and the soft parts cannot be thinned or pressed out without danger of necrosis with subsequent ulceration.

The Council finds that most of the quotations recorded in the references submitted as clinical evidence are not pertinent to the matter under discussion, particularly those referable to pressure, atrophy and distortion. Most of the references to medical literature are taken from textbooks several years out of date.

One cannot draw analogy from the effects of pressure on joints or the spine as compared to the effects of pressure on the nose. The statements quoted in the references are not complete, which materially changes the meaning of the statements. Any changes, such as those involved in misshapen skulls or distorted feet of Chinese women or pressure as from intracranial tumors existing unremittingly over a long period, are constant in character and in most instances are applied to very young children during their growing or formative period, when bones are quite soft and the interstices between the segments have not yet filled in.

The suggestion that the intervertebral cartilages become triangular is a gross misrepresentation, as this does not occur from trauma or pressure except in the face of disease such as tuberculosis. The nucleus pulposus is incompressible and so elastic that the bone of the body of the vertebra will crush and change its shape long before the cartilage is in any way affected. Likewise the quotations covering the treatment in scoliosis saying that gymnastics and posture are insufficient—stretching and retaining apparatus are necessary—concern a question on which experts have not agreed. In the opinion of the Council, the Anita Nose Appliance cannot possibly be effective in molding or gradually reshaping soft parts of the nose thereby changing the general appearance. It would be impossible for any one to wear this appliance over a long period at a fixed degree of tension. The patient would have to take the device off at night or in the daytime to wash his face or for other purposes and any intermittent change in the pressure would invalidate the proposed claim by the manufacturer. Continued pressure would lead to irritation of the skin and to necrosis and ultimate ulceration.

As a means of holding on a dressing or protecting noses after reduction of fracture and displacement of the bones or cartilage or possibly in many cases for retention of the full thickness flaps against a raw area such a device might be useful. There are other devices that a physician can make himself at the time of his operation which are cheaper and have the qualities incidental to all custom made materials such as would be required in the fitting of nose no two of which are exactly alike.

The Council on Physical Therapy declares the Anita Nose Appliances unacceptable for inclusion in the list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS JEECH Secretary

LIQUID PETROLATUM (See New and Nonofficial Remedies, 1933, p. 255)

The following dosage form has been accepted:

Petrolagar with Cascara (Non Bitter) Liquid petrolatum 60 cc emulsified with agar in a menstruum containing non bitter fluid extract of cascara sagrada 13.2 cc sugar flavoring sodium benzoate 0.1 Gm and water to make 100 cc.

Prepared by the Petrolagar Laboratories Inc. Chicago. No U S patent. U S trademark 165 616.

RADIUM CHLORIDE (See New and Nonofficial Remedies, 1933, p. 342)

Radium Chloride-Radium Belge—Supplied in the form of a mixture of radium chloride and barium chloride containing 90 per cent or more of the radium salt. Sold on the basis of the U S Bureau of Standards measurement with the radium purity (concentration) guaranteed by the Radium Chemical Co., Inc., it is also guaranteed that the gamma ray activity due to the presence of mesothorium, radiothorium or substances other than radium and its derivatives does not exceed 0.2 per cent.

Manufactured by Radium Belge Union Miniere du Haut Katanga Brussels Belgium (Radium Chemical Co. Inc., New York distributor).

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

PAUL NICHOLAS JEECH Secretary

HORSFORD'S ACID PHOSPHATE NOT ACCEPTABLE FOR N N R

Horsford's Acid Phosphate was presented for consideration of the Council by the Rumford Chemical Works, Rumford, R. I. In the information submitted by the firm the value of the product is said to depend on the phosphoric acid and the calcium, sodium and potassium ions contained. In the advertising submitted it is stated that the product consists of an aqueous solution of phosphates of calcium, magnesium, potassium, sodium and iron with phosphoric acid. Elsewhere in the advertising it is said to consist of a solution of the phosphates of lime, magnesium, potash and iron in phosphoric acid. Neither the advertising nor the presentation states the amount of any of the constituents in this preparation but it is stated that it was invented [sic] by Professor E. N. Horsford, then Rumford professor of chemistry, Harvard 1847 to 1863. The submitted label contains the following more definite statement of composition: "A fluid drachm contains 3 3/4 grains calcium acid phosphate, 1 grain magnesium acid phosphate, 1/4 grain sodium acid phosphate, 1/2 grain potassium acid phosphate, 1/4 grain iron acid phosphate and 3 1/2 grains free phosphoric acid. Total phosphoric acid free and combined, 8 1/2 grains."

The advertising is a mélange of science and pseudoscience. Horsford's Acid Phosphate is recommended in a great variety of conditions, including the following: as a tonic; as a builder-up; in the run down conditions following prolonged illness; failure of proper nourishment from food; loss of appetite; lassitude and weakened or impoverished nerve energy; as an aid in the treatment of the prostrated condition resulting from the excessive use of alcohol to allay the insomnia resulting from the use of tobacco and other causes; in many nervous diseases brought on by nerve tire [sic] and exhaustion.

In support of the greater number of claims the manufacturer cites numerous articles from 1899 to 1892 but only three of later date than 1921. The Council's referee examined one of the later articles cited that of Poppelreuter (*Mitt. d. Naturh. Ver. 76* 912 [May 31] 1929). This article is based on Poppelreuter's work with heparin, a preparation of cod liver

biphosphate which the Council rejected (*THE JOURNAL* May 3 1930, p 1406) in part because the therapeutic claims advanced for it were unwarranted. The claims made for Horsford's Acid Phosphate in general are similar to those made for Recresal.

The Council declared Horsford's Acid Phosphate unacceptable for New and Nonofficial Remedies because it is an unscientific mixture of unproved usefulness marketed with unwarranted therapeutic claims and in such a way as to tend to its ill advised use by the public.

EDWENIL NOT ACCEPTABLE FOR N. N. R.

Edwenil is a product proposed for nonspecific immune therapy now marketed in the United States by Spicer and Company of Glendale, Calif. Judging from the many inquiries received from physicians it appears to have been the subject of an intensive advertising program begun by the originators of Edwenil, E. H. Spicer and Co. Ltd., of Watford Herts, England, and continued by the present American distributors.

Edwenil has been variously designated 'antibacterin,' 'a polyvalent antibacterial agent,' 'the biochemical successor to vaccines,' 'natural antibody,' 'a therapeutic active immunizing agent.' Its composition appears to be highly complex, as indicated by the following excerpts from the advertising:

Edwenil is the result of fifteen years work representing an effort to produce natural immunity or a polyvalent natural antibody. It is a calcic protein compound consisting of three elements as follows:

CALCIUM in the form of the bicarbonate which is apparently the form in which calcium is required for utilization by the immune body precursors.

A CALCIUM VEHICLE in the form of a nucleo protein.

AN UNATTACHED GLOBULIN ELEMENT obtained from serum.

EDWENIL is a complex organic colloid formed by a linkage of some of the alkali-denatured protein derivatives of normal serum and muscle in the presence of a normal saline containing calcium and magnesium salts.

As is usual with 'polyvalent' products of this sort this preparation is recommended as being of great value in a large variety of diseases among them, furunculosis tonsillitis, quinsy, otorrhea, leukorrhea, eczema, acne, impetigo, sycosis, bronchitis, bronchiectasis, bronchial asthma, pneumonia influenza, common cold, tuberculosis rheumatoid arthritis, early osteo-arthritis, sciatica, rheumatic fever, measles mumps whooping cough herpes, scarlet fever, chronic pyelitis and cystitis, cholecystitis, appendicitis, peritonitis, 'etc.' It is claimed to be quite devoid of toxic properties.

EDWENIL provides you with a non specific non toxic harmless and rapidly effective means of controlling endotoxic infections in general. It is readily absorbed without local or general reaction thus obviating all disadvantages of vaccine or protein shock therapy.

EDWENIL is absolutely non toxic and harmless.

Anaphylactic phenomena are not encountered.

Numerous case reports are presented in the advertising "literature," giving sketchy details of alleged cures following the administration of Edwenil many even miraculous.

In an article appearing in the *Prescriber*, Edinburgh (24 253 [July] 1930), the origin of this type of antibacterial agent is attributed to S. G. Billington of Leamington who is said to have discovered the 'antibody complex' which apparently goes to make up Edwenil. An extensive bibliography is quoted both of experimental and of clinical work. Unfortunately all these articles have appeared in a single journal published in London, the *Medical World*, a periodical not available in this country even at the Surgeon General's Library. It is indeed cause for wonder that almost the only available data from medical sources about so remarkable a discovery should be so obscurely buried in the literature and that practically the only information available to the medical profession of this country about the product should come from the advertising circulars distributed by the commercial exploiters of Edwenil. In all the latter material (and it is fairly voluminous) there is nothing referable to the use of this product that bears critical examination.

Only a single paper on Edwenil was found in the American literature, that by J. Montgomery Anderson of London in the *Medical Journal and Record* (136 1 [July 6] 1932). On examination a large part of this article was found to be identical word for word with a section of an advertising booklet issued by the English firm E. H. Spicer and Company Ltd.

The remainder of this uncritical effusion is devoted to completely uncontrolled clinical evidence of the same sort as that presented in the advertising material.

While its composition is apparently quite different, the claims made for Edwenil are very similar to those made for Omnadine, another preparation proposed for nonspecific immune therapy which has already been the subject of an adverse Council report (*J. A. M. A.* 100 1173 [April 15] 1933). Objections there stated to Omnadine apply with equal force to Edwenil.

If the complete absence of allergic reactions claimed for Edwenil is true it would appear that this product contains little, if any, antigenic material. With those preparations of definite high antigenic potency (*Bacillus typhosus* vaccine, for instance) reactions are known to occur in a certain percentage if not in all individuals treated. If Edwenil is as safe as it is claimed to be, either it represents an epoch-making advance in medicine or it is practically useless as an immunizing agent.

There is no reliable evidence available to the Council that Edwenil involves any advance in nonspecific immune therapy. The Council believes that it must be classed as a dangerous preparation. If it contains antigenic material, claims of complete safety in its therapeutic use must be considered reprehensible, even if it has only a trace of antigen it may yet cause allergic reactions and if it is devoid of antigenic potency its use is unwarranted and may carry a hazard in the neglect of more effective remedies.

The Council declared Edwenil unacceptable for inclusion in New and Nonofficial Remedies because it is apparently an unscientific preparation of semisecret composition (rules 1 and 10) marketed under an uninformative name (rule 8) with unwarranted and possibly dangerous therapeutic claims (rule 6).

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

VI-TO-MATO

CLEAR FILTERED TOMATO JUICE

Manufacturer—Tomato Products Company, Paoli, Ind.

Description—Pasteurized clear filtered tomato juice contains little vitamin A because of removal of tomato pulp; vitamin B is largely removed; vitamin C is equivalent to that of the unfiltered juice.

Manufacture—The tomato juice is prepared by essentially the same procedure as French Lick Tomato Juice (*THE JOURNAL* Aug. 13 1932 p. 563) excepting that practically all of the tomato tissue is removed by a second screening. The thin juice in large containers is heated to 88° C. the containers are sealed. After a storage period the juice is removed from the containers admixed with 'calcined filter aid,' filtered at a low temperature (approximately 4° C.) in a plate and frame press in the practical absence of air heated to 71° C., sealed in containers and processed at 93° C.

Analysis (submitted by manufacturer) —

	per cent
Moisture	96.7
Total solids	3.3
Ash	0.3
Fat	0.0
Protein (N x 6.25)	0.8
Crude fiber	0.0
Carbohydrates other than crude fiber (by difference)	2.2

Discussion of Name—The syllable *Vi* in connection with the name 'Vi-To-Mato' suggests 'vitamins' and thereby emphasizes the vitamin content of this filtered juice, which is inferior in vitamin content to the usual canned unfiltered tomato juice. The tomato juice largely retains the natural vitamin C but contains little of the natural vitamins A and B content. Although the filtered juice is inferior in vitamin content to unfiltered juice the contrary may be inferred from the name which is therefore misinformative and misleading.

The manufacturer was advised of the Committee's report but is not willing to change the brand name for business reasons. This product will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

IRRADIATED VITAMIN D PASTEURIZED MILK
ADVERTISING OF PRODUCERS
CREAMERY*Distributor*—Producers Creamery, Benton Harbor, Mich*Description*—Advertising for bottled pasteurized vitamin D milk irradiated by Steenbock Process (patent No 1,680,818)*Preparation*—The milk complies with the analytic and bacteriologic requirements specified by the laws of the state of Michigan and the cities of Benton Harbor and St Joseph or other municipalities in which it is distributed

The milk is irradiated by a "CP Carbon Arc Lamp Milk Irradiator" equipped with a recording ammeter for recording lamp energy input and output of the irradiator milk pump and provides a complete chart of operation for inspection by plant and health officials. The irradiated milk is pasteurized by the standard procedure (holding method thirty minutes, at 61 C), immediately cooled automatically bottled and capped. The bottled milk complies with the requirements of the state of Michigan and health departments having jurisdiction over its production, processing, bottling and distribution. The method of irradiation and the equipment are under scientific control.

The bottles are washed for eight minutes in an alkaline solution, rinsed, cooled and washed with chlorine water.

Analysis (submitted by manufacturer) —

	per cent
Moisture	86.8
Total solids	13.2
Ash	0.7
Fat	4.3
Protein (N \times 6.38)	3.4
Lactose (by difference)	4.8

Calories—0.8 per gram 22 per ounce

Vitamins—Clinical investigation shows this irradiated milk to be a reliable antirachitic agent protecting all infants excepting those prematurely born, contains 50 Steenbock vitamin D units per quart.

Claims of Manufacturer—An irradiated antirachitic pasteurized milk having the natural flavor and food values of standard pasteurized milk.

CAKE-MAKER FLOUR (BLEACHED)

Manufacturer—Federal Mill Inc, Lockport N Y*Description*—A "short patent" soft winter wheat flour, bleached.

Manufacture—Selected soft winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932 page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one twenty eighth ounce per 196 pounds) and with nitrogen peroxide.

Claims of Manufacturer—Specially prepared for cake, biscuit and pastry baking.

STOKELY'S FINEST MEDIUM GREEN
LIMA BEANSSTOKELY'S FINEST TINY GREEN
LIMA BEANS*Manufacturer*—Stokely Brothers and Company Inc, Louisville, Ky*Description*—Cooked graded fresh lima beans respectively medium and small sizes.

Manufacture—Fresh lima beans harvested at their height of development, are thrashed from the pod graded according to maturity washed cleaned of foreign material graded by machine into the three sizes: tiny, small medium and large medium, and inspected on white rubber belts for removal of

undesirable material and the separation of white and green beans. From this step on, each type of bean is separately handled.

The beans are blanched in hot water sprayed with fresh water automatically filled into cans, and covered with brine, the cans are sealed, processed for a definite period at 115 C, immediately cooled, and labeled.

Analysis (submitted by manufacturer) —

	per cent
Moisture	80.7
Ash	1.4
Sodium chloride (NaCl)	1.0
Fat (ether extract) —	0.3
Protein (N \times 6.25)	4.9
Crude fiber	1.2
Carbohydrates other than crude fiber (by difference)	11.5

Calories—0.7 per gram 20 per ounce

Claims of Manufacturer—Packed in enamel lined cans within a few hours after picking. Natural mineral and vitamin values are retained in high degree.

THE NEW PAN DANDY LOAF (SLICED)
BIG DANDY (SLICED)*Manufacturer*—The L D Feuchtenberger Bakeries, Bluefield, W Va

Description—White bread made by the sponge dough method (method described in THE JOURNAL March 5 1932 p 817) prepared from patent flour, water, sweetened condensed skimmed milk, sucrose, lard, salt, malt syrup, yeast and a yeast food containing calcium sulphate ammonium chloride, sodium chloride and potassium bromate.

DAILY BREAD FLOUR (BLEACHED)

Manufacturer—Federal Mill, Inc, Lockport, N Y*Description*—A "standard patent" Northwestern spring wheat and hard winter wheat flour, bleached.

Manufacture—Selected wheats are cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18 1932, page 2210. Chosen flour streams are blended, bleached with nitrogen trichloride (one-ninth ounce per 196 pounds) and with nitrogen peroxide.

Claims of Manufacturer—Intended for bread baking.

CLAPP'S ORIGINAL BABY SOUP (UNSTRAINED)
(ADDED SALT)*Manufacturer*—Harold H Clapp Inc Rochester N Y

Description—An unstrained cooked soup stock prepared from potatoes, tomatoes, carrots, unpolished rice, cabbage, celery, meat broth, whole grain barley, salt, onions and water. The method of preparation is efficient for retention in high degree of the natural vitamins and minerals.

Manufacture—The preparation is the same as for Clapp's Original Baby Soup (THE JOURNAL June 24, 1933, p 2011) except that the material is not strained.

Analysis (submitted by manufacturer) —Essentially the same as for Clapp's Original Baby Soup. The crude fiber can be expected to be higher.

Vitamins and Claims of Manufacturer—See Clapp's Original Baby Soup (THE JOURNAL, June 24, 1933 p 2011).

HENRY CLAY ROLLER EXTRACT FLOUR
(BLEACHED)CREAM ROLLER EXTRACT FLOUR
(BLEACHED)*Manufacturer*—Lexington Roller Mills Company, Lexington Ky*Description*—Soft red winter wheat "short patent" flours, bleached.

Manufacture—Selected soft red winter wheat is cleaned, washed, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL June 18 1932 page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one ninth ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (one fourth ounce per 196 pounds).

Claims of Manufacturer—For general baking in the home.

SURGICAL RELIEF OF CARDIAC PAIN

The recognition that deleterious effects caused by impulses traveling along fibers of the sympathetic nervous system may be prevented by severing the nerves surgically was a significant observation for the advance of medical science. These abnormal impulses vary; some produce serious arterial spasm, others smooth muscle inhibition and some convey intense sensations of pain of visceral origin. The pain in angina pectoris was among the first to lend itself to surgical procedures, and in many cases definite alleviation of pain occurred. Jonnesco,¹ in 1916, was the first to operate on these patients. He removed at first the lower two cervical ganglions as well as the first thoracic ganglion. Later he included the first cervical ganglion. The results, however, proved too uncertain to warrant extensive trial. In 1923 Coffey and Brown² asserted that removal of the superior cervical ganglion alone, or even division of its cardiac branches, was sufficient. As a result a number of patients were subjected to this relatively simple procedure, although neurologists in America asserted in general that no fibers carried pain impulses to the brain by way of this ganglion. Cutler,³ who analyzed the results up to 1927, found that but half of the patients operated on could be considered as presenting a good result, whereas the mortality ranged from 4 to 14 per cent. Mixer and White,⁴ in 1931, described clinical evidence pointing to the thoracic rather than the cervical sympathetic as an advisable site of surgical attack in cardiac pain.

Obviously, if the surgeon is to interrupt nerves carrying impulses giving rise to pain he should know accurately their pathway. This is possible if he can identify among the many different kinds of fibers present in a given nerve the ones actually concerned

with the transmission of pain. This is now possible as a result of recent researches, both physiologic and anatomic, made at the Washington University School of Medicine by Heinbecker, Bishop and O'Leary. These investigators have offered physiologic proof that impulses resulting in pain are mediated by myelinated fibers of the somatic type, from 3 to 6 microns in diameter. It is possible, moreover, to recognize these fibers in sympathetic nerve trunks stained with osmic acid. Using this information, Heinbecker⁵ has studied the nerves containing sensory fibers from the heart and first portion of the aorta. He finds that sensory fibers ascend in all three sympathetic cardiac nerves to enter the superior middle and inferior cervical ganglions. From here they enter the central nervous system in the fifth cranial nerve and the cervical gray rami communicantes. Afferent fibers from the heart also enter by the rami communicantes of the upper six or seven thoracic levels. These results afford an anatomic explanation for the beneficial results of Coffey and Brown. They show also the reason for a goodly percentage of failures by any of the usual procedures so far employed for the relief of the pain of angina pectoris. For instance paravertebral alcohol injections at the upper thoracic levels do not interrupt the afferent fibers in the middle and superior cardiac nerves.

The present outlook, Heinbecker states, presents many possibilities. Armed with the newer knowledge, it seems clear that selective surgery offers ample opportunities for the relief of many cases, particularly those of referred pain. It is considered axiomatic that pain is referred to the body levels at which the visceral fibers enter. The level at which pain is felt in cardiac disease should be carefully studied in each case in order to select the proper site for surgical attack. There are, of course, many cases in which the pain is not referred but felt only within the thorax beneath the sternum. Here, accurate selection is impossible and the stellate and closely associated ganglions constitute the most advisable point of attack, since histologic studies demonstrate that the largest number of afferent fibers course through this structure. If, however, after one procedure relief is not secured, further pain pathways must be severed, the same criteria being used again for determining the level of surgical attack.

Surgical advance is often hampered by the difficulties inherent in purely clinical study. The relief of cardiac pain is a particular case in point. Research into nerve physiology of the type being carried out by the St. Louis investigators points the way toward a more rational surgical attack in these cases. The more clinical medicine leans on such physiologic and anatomic studies, the greater will be the accuracy of predictable results.

TOOTH ENAMEL, DENTIN AND CARIES

Current knowledge of dental caries and particularly the etiologic factors involved are still the subject of profound confusion¹. This is true not only as it applies to the public and to physicians who observe caries incidentally, but even with respect to current interpretations by the dental profession. One reason for the existing confusion is that many persons fail to distinguish properly between caries and other dental maladies—an error that no dentist should commit. It would sometimes seem that each group of investigators is more intent on securing evidence for its own pet hypothesis than on establishing certain indisputable facts regardless of their immediate bearing.

The appealing aphorism that "a clean tooth never decays" has lost some of its pristine popularity. According to the White House Conference on Child Health and Protection,² studies more specifically directed toward the control of dental caries have recently emphasized that active caries should be definitely regarded as indicative of dietary deficiencies. The report cites the statement of Bunting that practically all students of the problem concur in the opinion that an adequate well balanced diet is inhibitive to this disease and advocate practically the same form of dietary procedure.

In current discussions the teeth are almost always classed, at least by nondental students of nutrition, along with the bones in any consideration of dental disorder. Physiology is quite well equipped at present to discuss the metabolism of the skeletal structures. Calcium and phosphorus, vitamin D and the parathyroid hormone are artfully woven into a story that is then passed on to the public in all sorts of ways. An uncritical reader soon visions a beautiful row of teeth without the carious blemishes that give so much concern. There are doubtless many delusions harbored on the basis of pseudoscientific guessing. At least one basis for securing a better understanding has recently been stressed by Martha Jones³ and her dental co-workers in Hawaii. They point out that a comparative study of enamel, dentin and bone in new-born and very young infants shows quite clearly that the formation of enamel and that of dentin in the unerupted teeth do not parallel each other but that those of bone and dentin do. Indeed this is to be expected they add since enamel is but an epithelial tissue arising in the ectodermal layer of the embryo, while bone and dentin are connective tissues originating in the mesoderm. The Hawaiian investigators allege that there often is a parallelism between the bone and the dentin forming mechanisms but an antagonism between the bone-dentin and enamel mechanisms.

Their observations indicate that the systemic factors controlling the formation and preservation of bone and dentin are identical but do not necessarily affect the enamel in the same direction. The results, they state, offer a logical explanation of why the teeth of children with marked stigmas of rickets are often well formed and free from decay, and why tooth decay may be rampant in rapidly growing, breast-fed infants in the tropics, with no evidence of rickets. It is helpful to realize adequately that bone-dentin and enamel forming mechanisms are not necessarily subject to the same factors.

According to Jones, in rickets the bone-forming mechanisms do not function properly, not because of an insufficiency of any bone-forming constituents in the diet, as is proved by the high incidence of the disease of babies fed on cow's milk, which contains much more calcium, phosphorus and vitamin D than human milk, but probably because of some "imbalance" that prevents the utilization of these elements. It may be that the "imbalance" is brought about under certain conditions by the excess of alkaline elements in cow's milk—a much greater excess than is found in human milk. The immediate hypothesis need not be hastily accepted that bone deposition thrives best under one potential reaction whereas the reverse seems to be true of enamel. The Jones thesis is that factors which accelerate calcification in the long bones, under certain conditions, may actually increase the liability of enamel to decay, and vice versa. The important aspect of the subject is to start thought along new channels where the devious ways have remained so confusing.

Current Comment

CAROTENE AND VITAMIN A IN BUTTER

Since the repeated demonstrations that a deficiency of vitamin A in the diet of experimental animals can be remedied by the inclusion of the natural pigment carotene, the view has developed that carotene is the precursor of vitamin A, being transformed in the process of metabolism in the animal body. Already investigations have been reported demonstrating the quantitative relationships between the pigment and the vitamin.¹ With the development of the subject, it has become obvious that the recognized vitamin A potency of many natural supplies of this food factor is due to one or the other of these substances or to a mixture of the two. Butter has from the first been considered a rich source of vitamin A and because of its color the question has frequently been raised as to the relative importance of the pigment in making up the total vitamin A potency. Brummann and Steenbock² have recently subjected this point to experimental study, butter made from cream collected in each month of the

year was examined for the content of carotene and of vitamin A by spectriographic analytic methods. Butter made in the summer contained a greater concentration of both the pigment and the vitamin than that made during the other seasons of the year, the difference between the April and August products being more than 100 per cent in both cases. However, according to the calculations of the Wisconsin investigators, only about 12 per cent of the total vitamin A potency of butter is accounted for by the carotene present. Since vitamin A can be looked on largely as a metabolic product from the carotene of the feed of the cow, these studies emphasize not only the extent of the transformation but also the ubiquitous distribution of the pigment. It would also appear from these studies that butter is of peculiar value as a source of vitamin A under conditions in which the absorption or transformation of carotene is faulty. Indeed, Dutcher, Harris and Guerrant³ have shown that vitamin A from a cod liver oil concentrate is better utilized in the presence of liquid petrolatum than is carotene. This observation, together with the observations of Baumann and Steenbock, provide valuable supplements to the current knowledge of the biologic relations of carotene and vitamin A, a topic that will doubtless receive much further attention from investigators in this field.

THE WATER CONTENT OF THE FECES

The widespread use of a great variety of laxatives and aperients in this country cannot fail to command the careful attention of the medical profession. Every household medicine chest includes one favorite prescription or more often some widely vaunted proprietary product of undescribed composition. The attack on constipation by the afflicted public involves the use of such diverse agents as bran, agar, phenolphthalein, cascara, castor oil and mineral salts—to mention a few products exhibiting unlike pharmacologic or physiologic actions on the alimentary tract. This raises, first of all, the question as to what constitutes a normal stool—a problem recently discussed in detail in *THE JOURNAL* by a group of investigators¹ at the Yale University School of Medicine. It is well established² that the final removal of water from the intestinal contents—their gradual desiccation so as to produce characteristic feces—occurs beyond the ileocecal valve. Studies by Steggerda³ at the College of Medicine of the University of Tennessee on experimental animals indicate that concentration of fecal material took place in the cecum and rectum, while a small amount of absorption was noted in the colon proper. Determinations were made also on human stools, the results showing that the feces in the rectum contain approximately 10 per cent less water than those lying in the colon just proximal to the rectum. Roentgenograms show that fecal

material is lodged in the rectum long before the desire to defecate is felt. Obviously these facts have an important bearing on the relief of certain types of constipation or, on the other hand, the prevention of objectionable diarrheas.

VIRULENCE OF MILK-BORNE BACTERIA

Clinicians trained in the conventional law of bacterial adaptation will receive Shope's¹ report of a paradoxical adaptation of the pseudorabies virus with skepticism. Yet his report is characteristic of a mass of unconventional data now being gathered by competent research specialists. Dr Shope claims that repeated passage of this virus through a new animal species may reduce its pathogenicity for this species without demonstrable changes in its infectivity for its original animal host. His studies were made with a strain of "mad itch" virus, almost invariably fatal for both rabbits and guinea-pigs when given either intracerebrally or subcutaneously. Death usually occurs within sixty to eighty hours. Repeated rabbit passage is without demonstrable effect on its infectivity for either animal species. Guinea-pig passage, however, markedly decreases its guinea-pig infectivity, subcutaneous tests with multiples of the previous minimum lethal dose causing no demonstrable symptoms in 95 per cent of the cases. The virus still remains fully virulent for rabbits. Analysis of this animal-specific reduction in pathogenicity shows that it is not due to a specific antibody mechanically carried in the infectious material. Dr Shope's result is timely in its bearing on the much discussed problem of the probable virulence of milk borne bacteria.

COMBINED ARSPHENAMINE-ULTRAVIOLET THERAPY

The possibility of increasing the therapeutic effects of arsenicals by the simultaneous use of ultraviolet rays has been extensively studied during the last three years by European investigators. Orlov and Lewinson¹ of the venereal institute at Moscow studied the curative effects of combined arspenamine-ultraviolet therapy on experimental syphilis in rabbits. They report that ultraviolet radiation increases the spirocheticidal effects of neoarsphenamine and does not demonstrably increase its toxic effects. It causes substerilizing doses of the arsenical to become therapeutically effective. They unhesitatingly recommend its clinical trial. A definite rationale for this combination therapy has been suggested by other investigators. Roskin and his co-workers,² for example, state that exposure of mice to ultraviolet radiation causes a new immunity factor to appear in the blood stream. This "factor" is without direct effect on trypanosome infections. Transferred to nonirradiated mice, however, the factor greatly increases the trypanocidal action of arsenicals. From a study of splenectomized and endothelial-blockaded mice they believed that the new factor is formed or secreted by the reticulo-endothelial cells.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock central standard time, over Station WBBM (770 kilocycles, or 389.4 meters)

The subjects for the week are as follows

October 10 Anemia
October 12 Guaranteed Cures

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM

The subject for the week is as follows

October 14 Diphtheria

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

ALABAMA

Personal—Dr Ralph D Neal has been appointed health officer of Monroe County, succeeding Dr Thomas E Tucker, who resigned, September 1. Dr Neal was formerly health officer of Clarke County, with headquarters in Grove Hill. Dr Reuben J Guest, Jr, Fort Payne, has been appointed health officer of DeKalb County, succeeding Dr Lee Weatherington, resigned.

Society News—At a meeting of the Bullock County Medical Society in Union Springs, August 9, the speakers were Drs Charles M Franklin on "Malaria as a Complication", Clark Hilton Rice, Montgomery, "Treatment of Habit Spasms by Psychotherapy," and Alfred A Walker, Birmingham, "Prophylaxis and Treatment of Infectious Diarrhea." The Elmore and Tallapoosa county medical societies were addressed at their annual joint meeting recently, among others by Drs Archie E Thomas, Montgomery on "Conservative Treatment of Eclampsia", James Harold Watkins, Montgomery, "Cardiac Failure Associated with Pain" and Lewis H Hamner, Camp Hill, "Abnormal Blood Pressure." At a recent meeting of the northeastern division of the Alabama State Medical Association, the speakers included Drs James O Morgan, Gadsden, on "Hormone Test for Pregnancy," and Louise H Branscomb, Birmingham, "Hormone Therapy in Gynecology."

ARKANSAS

Dr Brooksher Elected State Secretary—Dr William R Brooksher Jr, Fort Smith was elected secretary-treasurer of the Arkansas Medical Society at a meeting of the council in Little Rock, September 15. Dr Brooksher fills the unexpired term of the late Dr William R Bathurst Little Rock.

Society News—Speakers before the Tenth Councilor District Medical Society, September 12 included Arthur M Harding, PhD, University of Arkansas, Fayetteville on "Education and the New Deal" and Drs Leonce J Kosmusk, Texarkana "Aspects of Organized Medicine", Frederick H Krock, Fort Smith "Peripheral Vascular Disease", William A Fowler, Fayetteville, "Birth Injuries" and Joseph W Larmore, St Louis "Differential Diagnosis of Diseases of the Right Colon." The Conway County Medical Society and the Yell-Pope County Medical Society recently combined to form the Tri-County Medical Society and the first meeting of the new group was held in Russellville August 10.

CALIFORNIA

Mussel Poisoning—Seven cases of mussel poisoning occurred in Redwood City July 8 among persons who had eaten mussels gathered at Half Moon Bay the bulletin of the state health department reported.

Course in Medical Statistics—Dr Emil Bogen Olive View, began a course of lectures, September 20, at the Los Angeles County General Hospital, on medical statistical methods. Tentative plans call for six lectures. No fee is charged.

Changes in Health Officers—Dr Harold E Morrison, formerly with the Los Angeles school department, has been appointed health officer of San Mateo County, succeeding Dr Frank Holmes Smith, San Bruno. The county has a new county charter which gives the health officer additional duties relating to indigent relief, charities and similar activities. Dr Albert H Newton, Yreka, has been appointed health officer of Siskiyou County to succeed Dr Charles Pius. The city of Burbank has contracted with the Los Angeles County Health Department for the administration of its public health effective September 1, with headquarters in the Glendale Health Center. Dr Gilbert H Johnson has been appointed health officer of Mono County, succeeding Dr Gilbert A Kelley, Bridgeport.

Society News—Dr William J Kerr, San Francisco was the speaker at a joint meeting of the Los Angeles County Medical Association and the section on internal medicine, October 5, on "Clinical Application of Methods for Testing the Functional Capacity of the Liver." Dr Kerr addressed the San Diego Academy of Medicine, October 2 and 3 on "Diseases of the Liver and Liver Function Tests" and "Clinical Observations on Deficiency Diseases," respectively. At a meeting of the Symposium Society, Los Angeles, September 27, peritoneoscopy was discussed by Drs John C Ruddock and Albert J Scholl, Jr, Los Angeles. Speakers before the Los Angeles Clinical and Pathological Society, September 28, included Drs Ernest M Hall and George Lawrence Chaffin on "Malignant Adenoma of Parathyroid Gland." A joint meeting of the Los Angeles Society of Ophthalmology and Otolaryngology and Long Beach Eye and Ear Society, September 27, at Long Beach, was addressed, among others, by Dr Howard C Naffziger, San Francisco, on "Surgical Experiences with Ocular Myopathies and Intra-Orbital Tumors."

COLORADO

State Medical Election—Dr Gerald B Webb, Colorado Springs, was installed as president of the Colorado State Medical Society at its annual meeting in Colorado Springs in September, and Dr Nicholas A Madler, Greeley, was chosen president-elect. Other newly elected officers include Drs Frank E Rogers, Denver, Arthur G Taylor, Grand Junction, Clarence E Sidwell, Longmont, and Ward C Fenton, Rocky Ford, vice presidents, and John S Bouslog, Denver, constitutional secretary. Re-elected officers are Dr Leo W Bortree, Colorado Springs, treasurer, and Mr Harvey T Sethman, Denver, executive secretary. The next annual session will be held at Colorado Springs in September, 1934. The constitution was amended at this meeting to increase the number of councilor districts of the society from five to nine, with a view to reducing the amount of travel required of councilors. In accordance with a recommendation of the Committee on Cancer Education a new committee of the same name will be appointed to conduct a series of cancer symposiums before the county medical societies. The society appropriated \$300 to be used by the administration of the University of Colorado School of Medicine and Hospitals to change the system of admissions to Colorado General Hospital.

CONNECTICUT

Program to Detect Tuberculosis—The New Haven departments of health and education will conduct another program in the city schools this fall in effort to detect tuberculosis in school children. While the plan used last year for the mass examination of children will be repeated (THE JOURNAL, March 11, p 745) the method will differ in that greater effort will be placed on known contacts. Chest roentgenograms of children will be taken for which parents will pay reduced charges through special arrangements. The Connecticut Health Department plans to initiate a similar tuberculosis campaign throughout the state this fall (THE JOURNAL, August 5, p 453).

DELAWARE

Tumor Clinics—Each county in the state now has a tumor clinic at one or more hospitals as a part of the program of statewide cancer control approved by the Delaware Committee of the American Society for the Control of Cancer at its annual meeting January 11. Staffed by selected groups of local physicians the clinics and a free tissue diagnosis service are each under the general management of one person who is also the pathologist. The clinics are operated uniformly in an advisory

capacity only, without financial gain to the sponsoring institution and without expense to the referring institutions and physicians. Patients are referred back to their own physicians or hospitals, and letters are sent giving the opinion of the clinic as to diagnosis and recommendation for treatment. The clinics meet once a month or once in two weeks, depending on the size of the hospital.

DISTRICT OF COLUMBIA

Davidson Lecture—Dr Edwin A. Merritt will deliver the Davidson Lecture, October 11, on "X-Ray Treatment of Bone Conditions Produced by Hyperparathyroidism." The lecture was established by the Medical Society of the District of Columbia in 1929 as a memorial to Dr Edwin Young Davidson, a former president (THE JOURNAL, June 17, p 1942). It is given every two years.

Changes in Faculty at Georgetown—Dr George H. Hansmann, assistant professor of pathology, State University of Iowa College of Medicine, Iowa City, has been appointed associate professor at Georgetown University School of Medicine, Washington. Dr James A. Gannon has resigned as associate professor of surgery, after twenty-five years association with the department.

GEORGIA

Meeting of Pediatricians—The first annual scientific meeting of the Georgia Pediatric Society will be held in Atlanta, October 12, under the presidency of Dr Joseph Lampolsky. The following program has been announced:

Dr. Arthur F. Abt, Chicago: Use of Carbohydrates in the Diet and Treatment of Infants.
Dr. Horton Casparis, Nashville, Tenn.: Allergy in Children.
Dr. Charles G. Kerley, New York: A Demonstration Relating to Gastrointestinal Tract Anorexia and the Different Forms of Ptoisis Mucosa Gastritis and Intestinal Dysfunction.

A symposium on tuberculosis in children will be conducted by Drs. Casparis, James J. Clark, Atlanta, and Kellie N. Joseph, Alto. The Fulton County Pediatric Society will be host to the Georgia Pediatric Society and the Fulton County Medical Society at a buffet supper preceding the evening session. Dr. Walter E. Barber, president of the county medical society, will give the welcoming address, and Dr. William A. Mulherin, Augusta, the response. Drs. Casparis and Abt will discuss "The Mental Health of Children and Anemias of Infants," respectively, and Dr. Kerley will present a symposium on the tired child.

ILLINOIS

Society News—At a meeting of the DeKalb County Medical Society, September 28, Dr. Clement L. Martin, Chicago, spoke on anorectal diseases. Dr. Francis E. Seneat, Chicago, discussed "Role of Fungus Infections in Dermatology," before the Will-Grundy Medical Society, Joliet, September 27.

Health Surveys—Arrangements have been completed by the Illinois State Health Department to survey the health work and needs of schools in Elgin, Nokomis, Litchfield, Lebanon, Newton, Oblong, Altona and Browning, as a part of a statewide health program. The school surveys, which are made on request, are conducted by Dr. Robert C. Cook of the division of child hygiene.

Chicago

Society News—Speakers before the Chicago Council of Medical Women, October 6, were Drs. Alice K. Hall and Georgiana D. Theobald on "Treatment and Education of the Profoundly Deaf Child" and "Ocular Tumors in Children," respectively. At a meeting of the Chicago Pathological Society, October 9, Dr. Edward H. Hatton will give his official address as president on "The Origin and Pathologic Significance of the Epithelium Found About the Roots of Teeth."

INDIANA

Personal—Under a recent reorganization of the Indiana State Board of Medical Registration and Examination by Governor McNutt, Dr. William R. Davidson, Evansville, has again been appointed secretary. New members include Dr. Leslie C. Sammons, Shelbyville; Dr. Norris E. Harold, Indianapolis; and Earl O. Peterson, D.O., LaPorte.

Society News—Dr. Herman L. Kretschmer, Chicago, conducted a clinic before the Elkhart County Medical Society at Elkhart, September 7. The Gibson County Medical Society, Princeton, heard Dr. Oliver O. Alexander, Terre Haute, discuss industrial surgery, September 11. Speakers before the Tippecanoe County Medical Society, Lafayette, September 14, were Drs. Max A. Bahr and Walter L. Bruettsch, Indianapolis, on epidemic encephalitis and parkinsonism, respectively.

Dr. Karl M. Koons, Indianapolis, discussed goiter with special reference to borderline cases before the Huntington County Medical Society at Huntington, September 5. At a meeting of the Kosciusko County Medical Society, Warsaw, September 12, Drs. C. Norman Howard, Warsaw, and Charles E. Thoma, Leesburg, spoke on encephalitis. A symposium on pulmonary tuberculosis as the general practitioner sees it was presented before the Hancock County Medical Society, recently, the speakers were Drs. Charles E. McCord, Samuel W. Hervey, Jesse C. Ferrell, Stewart Slocum, and Byron J. Deakyn, DDS, all of Fortville. Speakers before the Indianapolis Medical Society, October 3, were Drs. Dunn Hamilton, Row and William F. Clevenger, on "Detachment of the Retina" and "Modern Phases of Sinus Abnormalcy," respectively. Dr. Walter F. Kelly, president, also spoke. Among others, Drs. Norris E. Harold and Walter C. Pennington will address the society, October 10, on "Polycythemia Vera" and "Study of Gastric Rugae," respectively. A symposium on orthopedics will be presented before the society, October 17, one on birth control, October 24, and one on diet, October 31.

IOWA

Society News—The Hardin County Medical Society heard Dr. Melvin W. Binger, Rochester, Minn., discuss nephritis recently. Dr. Walter L. Biering, Des Moines, President Elect, American Medical Association, was the principal speaker at the annual picnic of the Second Councilor District Medical Society at Clear Lake, August 18, on the history of medicine.

KENTUCKY

State Medical Election—Dr. Carl C. Howard, Glasgow, was chosen president-elect of the Kentucky State Medical Association at the annual meeting in Murray, September 14, and Dr. W. M. Martin, Harlan, was installed as president. Vice presidents elected were Drs. Henry G. Sandlin, Richmond; John C. Morrison, Hickman; and Edward R. Palmer, Louisville. Dr. Arthur T. McCormack, Louisville, was reelected secretary. The 1934 meeting will be held in Harlan.

Society News—Drs. Ellis S. Allen and James H. Pritchett, Louisville, addressed the Christian County Medical Society, Lafayette, August 31, on "Blood Transfusion and Its Various Aspects" and "Summer Diarrhea in Children," respectively. Dr. Louis Frank, Louisville, among others, addressed the Third District Medical Society at Bowling Green, August 23, on cancer of the cervix. Drs. David W. Heusinkveld and Gordon F. McKim, Cincinnati, among others, addressed a combined meeting of the Licking Valley and Mason County medical societies in Maysville, September 20, on pulmonary tuberculosis and a new operation for nephroptosis, respectively. At a meeting of the Jefferson County Medical Society, September 18, Dr. Ira N. Kerns, Louisville, discussed traumatic surgery and Mr. Charles Morris, "The Doctor on the Witness Stand."

LOUISIANA

Fall Clinic Canceled—At a special meeting of the Shreveport Fall Clinic Association, August 31, it was decided to cancel the fourth annual fall clinic, to have been held this year. The reason given for this action was that the Fourth District Medical Society, the Tri-State Medical Society and the Louisiana State Medical Society are all scheduled to meet in Shreveport.

MAINE

Society News—The Androscoggin County Medical Society was addressed at Lewiston, August 25, by Dr. Joseph H. Pratt, Boston, on "The Medical Profession in the Control of Tuberculosis." Speakers before the Kennebec County Medical Society at Belgrade Lakes, September 7, were Drs. Warren E. Kershner, Bath, president state medical association, and Forrest C. Tyson, superintendent of the state hospital, Augusta. At a meeting of the Waldo County Medical Society in Belfast, recently, the speakers were Drs. Arthur Paul Wakefield, Fairfield, on results in lung surgery, George W. Holmes, Boston, advances made in X-ray diagnosis and treatment, Eugene H. Drake, Portland, uses of the electrocardiograph in diagnosis, and William A. Ellingwood, Rockland, sinuses. The Washington County Medical Society was addressed, August 23, by Drs. Hugh A. Farris, St. John, N. B., on "Can the Electrocardiograph and X-Rays Be of Value to the General Practitioner?" Harrison V. Robinson, Bangor, "Exophthalmic Goiter," Russell J. Collins, St. John, "Changing Viewpoints Regarding Tuberculosis." Warren E. Kershner, Bath, present conditions in the state medical association and James H. McCurdy, Springfield, Mass., heart conditions.

MARYLAND

Pasteurized Milk—A regulation limiting the sale of milk to products that are pasteurized or certified, recently adopted by the Baltimore Health Department, became effective, September 1.

Meat Inspection Ordinance Amended—*Baltimore Health News* announces the following changes among others, brought about by a recent amendment of the meat inspection ordinance.

Persons processing meat, such as curing in large quantities cooking and smoking meat products and those manufacturing meat food products shall obtain a license.

Persons who operate a meat business in the counties and desire to sell their products in Baltimore are required to pay charges for inspection.

Route trucks operating in the city selling to the consumer must now obtain a license and in addition comply with the regulations governing the retail sale of meat products.

All renderers and collectors of bones and fat are brought under health department supervision and control.

All out of state shippers of meat products who desire to sell in Baltimore are required to obtain a license and to comply with regulations governing their shipments into the city.

MASSACHUSETTS

Personal—Dr Robert S Qumby, Watertown, has been appointed employment director of the state—Dr Samuel T Ladd, Portsmouth, N H, has been named comptroller of customs at Boston.

Memorial to General Wood—A memorial tablet will be unveiled in the new Harvard Memorial Church October 9 in honor of the late Major Gen Leonard Wood, former chief of staff of the United States Army and governor general of the Philippines. The tablet was recently placed in the church by sixteen men who served with him as aides-de camp. General Wood graduated from Harvard Medical School in 1884 and was awarded an honorary degree of doctor of laws in 1899.

MICHIGAN

Personal—Reuben L Kahn, D Sc, Ann Arbor, attended the immunologic conference in Rome, September 25-October 1 sponsored by the Volta Foundation of the Royal Academy of Italy. He presented two papers on 'New Serology of Syphilis' and 'Tissue Reactions in Immunity'.

Society News—Dr Cyrus C Sturgis, Ann Arbor, addressed the Calhoun County Medical Society, Battle Creek, September 5, on "Treatment of Secondary Anemia"—At a meeting of the Oakland County Medical Society, Pontiac, September 21, Dr Edward D Spalding, Detroit, spoke on 'Cardiac Disease, with Special Reference to Therapy'.

President's Night—In the future, the first regular meeting night in each month of the Wayne County Medical Society will be designated as 'President's Night'. October 2 marked the beginning of this practice and was in honor of Dr Alexander W Blain, the newly elected president of the society, who gave an address. Mr Albert Kahn, vice president of the Detroit Institute of Arts, where the society plans to hold its meetings in the future gave the address of welcome, and A M Smith Ph D, of the Detroit *News* spoke on 'The Philosophy of Medicine'. Mr Malcolm W Bingay executive director of the Detroit *Free Press* was presented with an honorary membership in the society at this meeting.

MINNESOTA

Practices Without License—Dr John G Halland pleaded guilty to a charge of practicing medicine without a license September 9 in the district court at Fergus Falls. Halland who had been practicing for two months at Pelican Rapids, was formerly licensed in Minnesota but his license was revoked in November, 1931, because of his use of narcotics (THE JOURNAL, Dec 19 1931 p 898). Halland was sentenced to six months in the Otter Tail County Jail but the sentence was suspended on his promise to return to his home in Fargo, N D and to obey the laws of Minnesota and North Dakota. He is to submit a written report to the court monthly until November, 1934 showing his whereabouts and occupation.

MISSOURI

Medal Awarded to Dr Goldstein—Dr Max A Goldstein, St Louis was awarded a medal for outstanding work in the study and rehabilitation of the deaf child at the recent annual meeting of the American Laryngological Rhinological and Otolological Society in Chicago. The award also included recognition of Dr Goldstein's recent book 'Problems of the Deaf'.

Personal—Dr Josephine B Neal of the New York City Health Department was guest of honor at a luncheon Sep-

tember 13, given by women members of the St Louis Medical Society. Dr Neal is in St Louis studying encephalitis—Dr Timothy S Bourke, Kansas City, was appointed a member of the state board of health, August 16, for a term of four years, succeeding Dr Herman S Gove, Linn, who resigned to accept an appointment as chief assistant to Dr Elmer T McGaugh, state health commissioner—Dr Henry Gettys was recently made medical director of the St Louis Police Department, succeeding Dr George W Becker.

Tumor Clinic Established—A tumor clinic was opened at the Fulton State Hospital, recently. For the present only ambulatory patients will be accepted for treatment. The clinic was established for the care of indigents only and since funds are not available for extensive social service work at the clinic itself, a rule has been adopted, providing for the certification of patients by a member of the Missouri State Medical Association and a recognized social agency. Following the adoption of a resolution by the State Eleemosynary Board August 14 to make radium at the Fulton State Hospital available for the treatment of cancer among the indigent, the cancer committee of the state medical association and the state hospital cooperated in the plan to establish the clinic.

NEBRASKA

Dr Riley Appointed Dean—Dr Bryan M Riley, professor of medicine, has been appointed dean of Creighton University School of Medicine, Omaha to succeed the late Dr Herman von W Schulte. Dr Riley has been serving as assistant to the Rev John J McInerney, regent of the university, who has been acting dean since Dr Schulte's death in July, 1932. Dr Riley was graduated from Creighton in 1900, served as instructor in medicine from 1905 to 1907 and later was appointed professor and head of the department of medicine. He was secretary of the administrative board of the university for thirty-two years. Dr Adolph Sachs, professor of medicine, succeeds Dr Riley as head of the department. He has been a member of the faculty since his graduation from Creighton in 1907. At present Dr Sachs is president of the Nebraska State Medical Association and the Omaha Mid-West Clinical Society.

NEW YORK

Society News—Dr Stanley E Alderson addressed the Medical Society of the County of Albany, September 27, on 'Surgical Infections of the Lung and Pleura'—The annual conference of sanitary officers and school physicians of the state of New York was held in Syracuse, September 27. Among speakers were Drs Frederick W Sears, Syracuse, on immunization of children with parental blood, Charles G Lenhart, Spencerport, relation of the general surgeon to the health officer and George H Ranisev of the state health department, Albany, communicable disease control in schools. At an evening meeting Drs Frederick H Flaherty, Syracuse, president, Medical Society of the State of New York, and Thomas Parran Jr, Albany, state health officer, among others, spoke on 'The Physician and Health Officer' and 'Milk Control' respectively.—Dr Eugene F Traub, New York addressed the Medical Society of the County of Nassau, September 26, on 'Ringworm Eczema and Dermatitis. Newer Methods of Treatment' and Hon Leone D Howell organizer of the Nassau Clearing House Association 'Inflation as It May Affect the Doctors'—The annual conference of the secretaries of component county societies of the Medical Society of the State of New York was held in Albany September 13. Medical relief under welfare programs and hospital dispensary problems were discussed.—The New York State Association of Public Health Laboratories will hold its midyear meeting at the state laboratory in Albany, November 3.

New York City

Friday Afternoon Lectures Begin—The fall series of Friday afternoon lectures sponsored by the Medical Society of the County of Kings began October 6 with an address by Dr Foster Murray Brooklyn, on present-day management of pulmonary tuberculosis. Dr William W Hala will speak October 13, on 'Laboratory Tests in the Diagnosis of Disease'. Dr Leo Loewe October 20 on rheumatism, and Dr William H Price October 27 on the rectum.

Beaumont Centennial Meeting—The first fall meeting of the New York Academy of Medicine October 5 was devoted to the celebration of the one hundredth anniversary of the publication of William Beaumont's 'Experiments and Observations on the Gastric Juice and the Physiology of Digestion'. Surg Gen Robert L Patterson of the U S Army presented a paper on Beaumont as an army officer. Dr Harris A

Houghton, a reading from the Beaumont-St. Martin contract, and Dr. Walter B. Cannon, Boston, discussed "Beaumont's Book After a Hundred Years." An exhibition of books and other memorabilia relating to the works, life and travels of Beaumont was shown.

OHIO

Lectures on Abnormal Psychology—Dr. Maurice Levine, assistant professor of psychiatry, University of Cincinnati College of Medicine, began, September 26, a course of evening lectures on abnormal psychology.

Health Survey of Hamilton County—Dr. Joseph L. Mountain, surgeon of the U. S. Public Health Service, has begun a survey of public health activities in Cincinnati and Hamilton County at the request of the bureau of governmental research. The survey will include the health departments, hospitals, clinics, school health and other activities in the health field.

Society News—Dr. Anderson Hilding Duluth, Minn., will address the Academy of Medicine of Cincinnati, October 9, on "Physiology of the Upper Respiratory Tract in the Light of Some New Research Developments." Dr. William J. Bleckwenn, Madison, Wis., will speak, October 16, on encephalography. Dr. Hilding will also present a paper before the Cincinnati Oto-Laryngological Society, October 10, on "Defense of the Nasal Mucosa Against Bacterial Invasion."

PENNSYLVANIA

Society News—The library of the Pittsburgh Academy of Medicine recently reported that, during the year ended June 6, 1941 books were lent and 1,748 reference questions answered. The library contains 13,000 volumes.—Dr. Francis C. Grant, Philadelphia, addressed the Warren County Medical Society, August 21, on "Head Injuries."

Practitioners Honored—Drs. Fayette L. Inslee, LeRaysville, and Phillip B. Williams, Pottersville, were guests of honor at a dinner given by the Bradford County Medical Society and other friends in their communities, August 7, as a testimonial to their thirty-five years of service. Dr. Stanley D. Conklin, secretary of the county society, presided and Dr. Donald Guthrie, Sayre, president-elect of the Medical Society of the State of Pennsylvania, made the principal address.

Philadelphia

Society News—Dr. Andrew MacPhail, professor of medical history, McGill University Faculty of Medicine, Montreal, delivered the thirty-first Mary Scott Newbold Lecture of the College of Physicians of Philadelphia, October 4, on "The Reading of History."—An eye section has been organized in the Philadelphia County Medical Society, with Dr. Charles R. Heed as chairman and Dr. Sidney L. Olsho, secretary.

RHODE ISLAND

Dr. Leonard Retires—Dr. Charles H. Leonard, a member of the staff of the health department of Providence for sixty-three years, resigned in August at the age of 91. He had been in charge of vaccinations for the department since 1870, two years after his graduation from the College of Physicians and Surgeons of Columbia University, New York.

Society News—Members of the Rhode Island Medical Society were guests of the State Public Welfare Commission at the State Hospital for Mental Diseases, Howard, September 7. Dr. Arthur P. Noyes, superintendent of the hospital, spoke on present-day conceptions of mental disease and members of the staff demonstrated various forms of mental disease.

SOUTH CAROLINA

Professor of Anatomy Appointed—Arthur Marvel Lassek, Ph.D., Chicago, has been appointed professor of anatomy at the Medical College of the State of South Carolina, Charleston, to succeed Dr. William F. R. Phillips, retired. Dr. Lassek received his advanced degree at Northwestern University, Chicago, in 1931 and taught anatomy at the University of South Dakota School of Medicine the following year. During 1932-1933 he was studying at Northwestern toward a degree in medicine. Dr. Phillips was professor of anatomy at the Medical College of South Carolina for about eighteen years.

Society News—Dr. Calvin C. Applewhite of the U. S. Public Health Service addressed the Orangeburg Medical Society, August 31, on typhus and allied conditions. This society is composed of physicians of Bamberg, Calhoun and Orangeburg counties.—Speakers at the annual meeting of the

Seventh District Medical Association at Happy Haven near Kinston, included Drs. J. Heyward Gibbs, Columbia, S. C., "Differential Diagnosis of Hookworm Disease and Duodenal Ulcer," Charles J. Lemmon, Sumter, "Fractures of the Humerus," Robert E. Abell Chester, president, South Carolina Medical Association, "Future of Our State Medical Association," and William Lgleston, Hartsville, "Organized Medicine."

TENNESSEE

Health at Memphis—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended September 21, indicated that the highest mortality rate (19) appeared for Memphis and the rate for the group of cities, 9.8. The mortality rate for Memphis for the corresponding week of 1932 was 13.9 and for the group of cities, 9.6. The annual rate for the eighty-five cities for the thirty-three weeks of 1933 was 10.9 as against a rate of 11.2 for the corresponding period of 1932. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

UTAH

State Medical Election—Dr. David C. Budge, Logan, was chosen president-elect of the Utah State Medical Association at the annual meeting in Salt Lake City, September 12, and Dr. Francis A. Goeltz, Salt Lake City, was installed as president. Vice presidents elected are Drs. Earnest P. Mills, Ogden, John G. McQuarrie, Richfield, Mabel Skolfield, Salt Lake City, Dr. Leland R. Cowan, Salt Lake City, was reelected secretary and Dr. Franklin H. Raley, Salt Lake City, treasurer. The 1934 meeting will be held in Salt Lake City in conjunction with the meeting of the Pacific Northwest Medical Association.

WASHINGTON

State Medical Election—Dr. Carroll L. Smith, Spokane, was elected president of the Washington State Medical Association at the annual meeting in August. Dr. J. Reid Morrison, Bellingham, vice president, and Dr. Curtis H. Thomson, Seattle, secretary, were reelected. The next annual session will be held in Spokane.

GENERAL

Nutrition Institute Reorganized—The American Institute of Nutrition has been reorganized within the past year to function as a scientific society. It was originally founded to own and publish the *Journal of Nutrition*, but, under the new arrangement, the journal will be taken over in January by the Wistar Institute, Philadelphia. The membership of the reorganized institute has been expanded and plans made for an annual meeting, which for the present, will be in connection with, although not a part of, the Federation of American Societies of Experimental Biology. The institute now has 160 members, and its officers are Lafayette B. Mendel, Ph.D., New Haven, president; Henry C. Sherman, Ph.D., New York, vice president; and John R. Murlin, Ph.D., Rochester, N. Y., secretary. Dr. Murlin will continue as editor of the journal.

Western Obstetric Meeting—The third annual meeting of the Pacific Coast Society of Obstetrics and Gynecology is to be held in Portland, Ore., October 19-21, under the presidency of Dr. Albert Mathieu, Portland. Among speakers will be

Dr. William C. McKee, Los Angeles, "Essential Hypertension as a Complication of Pregnancy,"
Dr. Robert Glenn Craig, San Francisco, "Pelvic Pain,"
Dr. Theodore W. Adams, Portland, Ore., "Dysmenorrhea,"
Dr. Ludwig A. Emge, San Francisco, "Influence of Pregnancy on Tumor Growths,"
Dr. Albert W. Holman, Portland, Ore., "Eclampsia,"
Dr. Richard J. O'Shea, Seattle, "Chorio Epithelioma."

The morning of Friday, October 20, will be devoted to clinical and pathologic demonstrations at Multnomah Hospital by Portland physicians.

Vital Statistics of Large Cities—The New York City Department of Health recently compiled comparative vital statistics for thirty large cities of the United States, relating to a population of about 28 million. The figures for 1932, which were supplied by the health officers of the respective cities, gave a general death rate of 11.26 per thousand of population, birth rate, 15.88, and infant mortality, 53.66 per thousand live births. Boston had the highest birth rate, 21.83; San Francisco the lowest, 11.19. New Orleans had the highest death rate, 16.11; Detroit the lowest, 8.69. New Orleans also

had the highest infant mortality rate, 7572, Portland Ore, 3346. The health department's bulletin warns, however, against comparisons of crude death rates as measures of relative healthfulness of various communities. The age and sex composition of the population and the proportion of Negroes have a marked influence on the death rate. Many of the cities have also a considerable proportion of deaths among nonresidents because of the fact that the hospitals of these cities draw hospital patients from a large surrounding area.

Society News—Dr Curtis C. Mechling, Pittsburgh, was elected president of the American Proctologic Society at its recent annual meeting. Dr E. Jay Clemons, Los Angeles, was made vice president and Dr Frank G. Runyeon, Reading, Pa., reelected secretary. The 1934 meeting will be held in Cleveland, June 11-12. The twenty-fifth anniversary meeting of the Association of Surgeons of the Pennsylvania Railroad was held in Cincinnati, September 22-23. Among speakers were Drs. Walter E. Dandy, Baltimore, on "Diagnosis and Treatment of Lesions of the Cranial Nerve"; Harry E. Mock, Chicago, "Compression Fracture of the Spine"; and Fred H. Albee, New York, "Bone Carpentry." Dr Charles H. Gowan, Glendale, Calif., was elected president of the Aero Medical Association of the United States at the recent annual meeting in Chicago, and Dr David S. Brachman, Detroit, reelected secretary. The 1934 meeting will be held in Washington, D. C., September 1-3. Dr John H. Hale, professor of surgery, Meharry Medical College, Nashville, Tenn., was designated president-elect of the National Medical Association at the recent annual meeting in Chicago. The annual session will be held in Nashville in 1934. The annual meeting of the Society of Plastic and Reconstructive Surgery will be held in New York, October 16-18, at the New York Academy of Medicine and various hospitals. Dry clinics will be presented Monday at Sydenham Hospital and New York Post-Graduate Medical School and Hospital, Tuesday morning at Manhattan Eye, Ear and Throat Hospital and New York Hospital, and Wednesday morning at the Institute of Ophthalmology, Columbia Medical Center.

Association of Medical Colleges—The annual meeting of the Association of American Medical Colleges will be held in Rochester, Minn., October 30, and in Minneapolis, October 31-November 1. A symposium on the report of the Commission on Medical Education (the relation of the number of medical graduates to the public need) will open the meeting, Monday, with the following physicians as speakers:

Willard C. Rappleye, dean, Columbia University College of Physicians and Surgeons, New York.
William D. Cutter, Secretary, Council on Medical Education and Hospitals, American Medical Association, Chicago.
Charles R. Bardeen, dean, University of Wisconsin Medical School (representing the state university).
Charles C. Bass, dean, Tulane University of Louisiana School of Medicine, New Orleans.

A symposium, Tuesday, on the medical care of the American people, income and distribution of physicians, will be presented by the following speakers: Alphonse M. Schwitalla, S.J., dean, St. Louis University School of Medicine; Dr. Robin C. Buerki, superintendent, Wisconsin General Hospital; and Dr. Rav Lyman Wilbur, president, Stanford University, Calif. Dr. Fred A. Moss, Washington, D. C., will present a report of the committee on aptitude test, and the following speakers will also be included in the program:

Dr. Jennings C. Litzberg, Minneapolis, Administration of Internships.
Dr. Rufus Q. Goodwin, Oklahoma City, Administration of Clinical Clerkships.
Dr. Harold S. Diehl, Minneapolis, Demonstration of Student Health Activities in the University of Minnesota.
George R. Moon, Chicago, Relation of Certain Factors in the Student's Premedical Record to Success in Medical School.
Ida M. Cannon, chief, social service department, Massachusetts General Hospital, Social Case Teaching of Medical Students.
Drs. Reginald Fitz, Boston, and Maurice Pincoffs, Baltimore, Bedside Teaching of Medicine.
Dr. Frank S. Randles, Albany, N. Y., Study of Accomplishment of Students in High School, College and Medical School.
Reuben M. Strong, Ph.D., Chicago, Problems of the Lowest Third of the Student Body.

MEXICO

One Hundredth Anniversary of Medical Faculty—The one hundredth anniversary of the founding of the Faculty of Medicine of the National University, Mexico City, will be celebrated in October. There will be a week of "Medical Days," October 23-28, during which lectures, clinics and laboratory demonstrations will be given in public and private hospitals. The committee in charge of the centenary celebration has invited the governments of several countries and the principal universities of the world to send representatives and is preparing a program of entertainment. Dr. Alfonso Pruneda Ayenda, Brazil, 33, Mexico, D. F., is secretary of the committee.

Sept. 16, 1933

The State of the Public Health

The annual report of the chief medical officer of the ministry of health presents an examination of the effects of unemployment on the fitness of the nation. He points out that in estimating the effects of widespread unemployment on the physical features of the people a number of factors must be considered. In the first place there is the direct effect on the unemployed individual and his dependents, and in the second the indirect effect on the physical well being and even on the minds of the employed (through fear of unemployment or otherwise) and on the population generally, whether employed or unemployed. The harmful effect of unemployment may be exercised on its victim in various ways: (1) deprivation of an adequate diet, (2) the effect of idleness on a manual worker in rendering him unfit to resume his occupation owing to want of practice and loss of muscular tone, (3) the effect of worry in impairing bodily functions, (4) excessive sickness or incapacity. In these effects there is much that cannot be analyzed or tabulated. But the surest test of grave physical results is the mortality returns. Any long sustained physical pressure or stress of serious degree will ultimately be represented in a rise of mortality. In the face of protracted and gradually increasing unemployment until the present time the mortality of the country as a whole, with few exceptions, and even of the depressed areas themselves, has uniformly decreased. Nor is there any evidence of increased morbidity. The mortality rates for England and Wales in 1932 show the same steady and definite decline as has been observed since 1921. The total death rate in 1932 was the exceptionally low one of 12 per thousand. It has been steadily falling since 1871. The infantile mortality was also exceptionally low and only half that of 1901-1910. The deaths of children under 1 year of age began to decline in an extraordinary degree some twenty-five years ago and have continued to decline ever since, even in periods of economic depression. The great constitutional diseases have declined in the last ten years. Premature birth caused forty-seven per thousand deaths in 1923 and thirty-four in 1932. The corresponding figures for diseases of the nervous system are 107 and 84, for bronchitis and pneumonia, 149 and 113. There has been of course a corresponding increase in the proportional mortality of other diseases, but they furnish no evidence of physical deterioration.

The estimated midyear population of England and Wales in 1932 was 40,201,000. The natural increase of population in the last five years has fallen from about 200,000 in the first year of the period to 130,000 in 1932. The present rate is only 4.9 per thousand, compared with 14.5 in the period 1876-1880. As shown in a previous letter (July 15, p. 220) it is estimated that this fall will result in a cessation of increase of population in 1940, and after that in a decline. In 1932 the birth rate was the lowest on record. The five principal causes of death, with the proportion per thousand deaths, were: diseases of the heart and circulatory system, 264; cancer—malignant disease, 125; bronchitis, pneumonia and other respiratory diseases, 113; diseases of the nervous system, 84; all forms of tuberculosis, 69.

Food Adulteration

While the adulteration of food has gradually fallen during the last fifty years from 20 per cent of the samples taken for analysis to 5 per cent, a new problem of adulteration has arisen in the form of the scientific treatment of food by skilled chemists. As examples of a risk to health or debasement of nutritive value in commercial processes the following are cited:

(1) the fumigation of food with toxic gases to destroy insects, (2) the presence of heavy metals in foods derived from materials or containers used in their manufacture, (3) the increasing use of insecticides and fungicides in agriculture and horticulture, (4) the treatment of flour with bleaching and improving agents, (5) "fortification" of foods by addition of vitamins, (6) the uncontrolled exposure of food to ultraviolet rays, (7) the introduction of new synthetic colors and flavors. In connection with the last it is mentioned that the aroma of butter is produced by a culture of *Streptococcus cremoris*. The actual substance responsible for the odor has been identified as diacetyl. It can be manufactured artificially, and in aqueous solution is used to give aroma to butter deficient in this respect. But highly aromatic butter does not keep well and possibly the addition of synthetic diacetyl to butter to improve its aroma may defeat its own object by causing the butter prematurely to turn rancid.

Inquest Without a Body

What is believed to have been the first inquest in Ireland in the absence of the dead body was held at Gortahork, Donegal, in connection with the disappearance of Mr. A. Kingsley Porter, professor of fine arts at Harvard University. His wife stated that their married life was happy and that they had no financial or other worries. Her theory was that he must have slipped off a cliff and fallen into the water and been carried out to sea. Every effort to find him failed. A verdict of death by misadventure was returned. According to English law, which existed in Ireland up to the establishing of the Free State, the inquest is held on the body of the deceased and until recent years the coroner's jury was bound to view it.

Financing Hospitals by Sweepstakes

The financing of Irish hospitals by turning to account the gambling spirit of the world has been extraordinarily successful. Since the first sweepstake, in November, 1930, \$84,000,000 has been subscribed in nine sweepstakes. Of this, \$26,600,000 has been allotted to the hospitals and the remainder has been devoted to prizes, expenses and taxation by the Irish government. The money for the hospitals has been used not only for current expenses but also for reconstruction and improved equipment. Fifty hospitals made claims for medical, surgical and pathologic apparatus, for the repayment of loans and for endowment investments. It has been laid down as a principle in the administration of the funds accruing to the hospitals in these "fat" years of the sweepstakes that their managers must have an eye to the possibility of "lean" years and therefore establish endowment funds. Fifty-three hospitals are now on the sweepstake list and it is stated that with wise investment for endowment purposes they may never again have to depend as they formerly did, on uncertain and haphazard incomes. This advice as to endowment certainly seems necessary, for there are not wanting indications that the flow of money from all parts of the earth, attracted by the large prizes offered, will not always continue. Some people have expressed the view that the millions of dollars obtained from England for the support of Irish hospitals should be devoted to her own hospitals and rival sweepstake schemes have been suggested, but so far nothing has been done. Such sweepstakes are illegal in England and there is a good deal of opposition, both on moral and also on prudential grounds, to hospitals being financed in this way.

Test of an Alleged Cancer Cure

Physicians are accused of prejudice because they will not give a trial to the so-called remedies for cancer constantly vaunted by persons entirely ignorant of medical science. But here is what happens when the government intervenes. A company known as the Roberts Clinics Pty. Ltd. was recently formed in Australia, according to the *Lancet* to exploit an alleged cure for cancer. As the result of a number of incidents

that followed, the government of Queensland appointed a medical committee to investigate its claims. People suffering from cancer who desired to submit themselves to the "cure" were called for. Of those who applied, thirty-seven were examined. Sixteen were rejected by the committee as unsuitable, some not being cases of cancer at all and others being too far advanced. Of the remaining twenty-one the proprietors of the "cure," Mr. Roberts, rejected eighteen—a rather damaging commentary on his claims. The remaining three were treated in a hospital specially staffed and equipped for the purpose by the home department. Into a large infiltrating tumor of the face Roberts injected a fluid, some of which ran over the cheek and produced a burn of the second degree. In the opinion of the committee the condition of the tumor was made worse, the malignancy becoming more active. In a case of cancer of the rectum in a woman, an abscess was produced and she abandoned the treatment. A case of cancer of the stomach was treated by injecting some dilute acid through a stomach tube. No improvement followed and death occurred soon afterward. So much for the three cases. The report of the committee refers to the ignorance of the claimant of the simple facts of medicine and chemistry and criticizes the facility with which such a person can float a company and commercialize the treatment of such a disease as cancer.

PARIS

Aug. 23, 1933

Study of the Epidemiology of Syphilis

The regular session of the dermatologic convention at Strasbourg was devoted this year, to the study of the epidemiology of syphilis. It is interesting to compare opinions, since the regulation of the cities differs widely. Depending on the will of the mayor, prostitution is either unrestrained or is restricted to resorts under medical supervision. It is difficult to form a true opinion of the actual conditions. It appears that the closing of brothels in some cities by the mayors has no influence on the increase or decrease of cases of syphilis. The authorities are therefore undecided as to what course to take. When prostitution is unrestricted, venereal diseases, in the absence of medical supervision, develop unchecked. When prostitution is supervised by the authorities, clandestine prostitution increases, and this form is the most dangerous, for it is practiced in cafes and hotels. Such is the conclusion formulated by Dr. Carl of Lyons. In that city, J. Gate and P. I. Michel ascribe the increase of syphilis to the fact that one finds there more and more arsenoresistant persons. In Bordeaux, G. Mettges and P. Juha observed a diminution of syphilis, which they attributed to the work of the prophylactic centers. In their opinion, clandestine prostitution is much more dangerous than supervised prostitution. Medical supervision is necessary in a large city, especially in an ocean port. T. Thorel reported an increase in syphilis at Havre as well as distinct variations in its virulence, which, he noted, coincided with the virulence of other infections, such as typhoid. The parallelism in these curves of virulence, which is difficult to explain, deserves more intensive study. At Rouen, according to Mr. Payenneville, the curve of syphilis is frankly in inverse relation to the application of prophylactic measures. J. Benech and A. Spillmann observed that unemployment increases clandestine prostitution and favors the development of venereal diseases. Among women out of employment who turn to prostitution one finds a large number who are carriers of spirochetes without their having ever worried over the fact, whereas professional prostitutes are better acquainted with the dangers. At Marseilles, Caujour and P. Vigon had observed a frank diminution of syphilis up to 1932, since which time a

sudden increase amounting to 23 per cent has been noted, which fact they attribute to unemployment among women and to a neglect of treatment among men. At Strasbourg, where all brothels have been closed, in accordance with the decision of a communist mayor, Goubelle has not observed any increase of syphilis in the military population over which he has supervision, although it is true that the supervision has been more strict. In the French army, an infected soldier is compelled, on pain of punishment, to report the name of the woman who infected him, and that woman is immediately sought out by the police and forced to accept dispensary treatment. Most of the conventionists were of the opinion that this method should be made compulsory by suitable legislation. Parliament, however, has never consented to pass such a law for fear of trespassing on personal liberty. But that excuse is mere sophistry. The liberty of spreading a harmful malady among the social body should yield to higher considerations. Mr Kissmeyer of Copenhagen reported that syphilis is decreasing in Denmark, where the treatment of syphilis is compulsory and gratuitous. Mr Charles Laurent had noted an appreciable diminution of syphilis in the department of Loire and attributed it to the excellent organization of the police department and the dispensaries. Mr Bertin of Lille emphasized the gravity of syphilis of nonvenereal origin, which is often overlooked. Mr Lepinav reported the continued increase of syphilis in Morocco, and Mr Touraine had made the same observation in the French colonies of Africa, Asia and Oceania where the infection is due to native troops and to foreign laborers. He mentioned regions that had been exempt but in which the disease, imported usually by colonists, is now developing rapidly, being frequently communicated to transient seamen. Esquier and Chevalier reported an aggravation of syphilis in the maritime sections of Toulon where one observes they stated a new syphilitic every two days in the population of 40,000. The prophylactic ointments recommended to the seamen have but slight value. Jouha, Bague and Leonard of Bordeaux called attention to the frequency of uterine chancre unrecognized in prostitutes. Bizard deplored the lack of laws with which to deal with prostitutes under age who owing to ignorance disseminate syphilis among young workmen of the suburbs of large cities.

Memorial—A Bust of Widal

To perpetuate the memory of Prof Fernand Widal who died in 1929, former pupils have had erected a bust by the sculptor Landowsky in the clinic at the Cochin Hospital, where he gave the major part of his instruction and carried on his researches. Under the bust are engraved the titles of his principal works: "serodagnosis, cytodiagnosis, pathogenesis of edemas, azotemia, classification of nephritis, colloidoclasia." Imposing ceremonies were held at the dedication presided over by the minister of public health. Addresses were delivered by Professor Achard and Professor Bezançon, collaborators of Widal. Professor Lemierre his most eminent pupil and Dr Mourier, director of the Assistance publique in Paris.

Deaths

Dr Henry Thierry, honorary inspector of the hygienic services of the city of Paris, vice president of the Conseil d'hygiène et de salubrité of the département of the Seine and an active promoter of modernization of the municipal disinfection services, died of injuries received in an automobile accident at the age of 64.

Dr Paul Sollier, eminent psychiatrist, has died suddenly at the age of 70. A former pupil of Charcot under whom he had served as head of the clinic at the Hôpital de la Salpêtrière, he had published some excellent articles on hysteria, systematized delirium and kindred subjects. He had founded an important sanatorium for mental patients near Paris.

BERLIN

(From Our Regular Correspondent)

Aug 28, 1933

The Ethical Council of Physicians

In previous letters the project of establishing a federal ethical council of physicians was announced. The draft of the proposed legislation has been handed to the federal minister of the interior by Dr Wagner, the federal director of the medical profession of Germany. The federal chamber of physicians, to be created on the basis of the federal ethical council of physicians, will be the only organization in which the German physicians will be associated for the fulfilment of their professional obligations. The result of this legislation will be that the previously existing independent professional leagues will be forced to disband. Within the federal chamber of physicians, some groups of physicians who have to perform certain tasks in public health administration, more particularly the panel physicians will be brought together in more intimate association. An important step in this direction has been taken through the recent executive order of the federal minister of labor in regard to the creation of the *Kassenärztliche Vereinigung Deutschlands* (association of the panel physicians of Germany). All panel physicians must be members of this association, likewise, all physicians whose names are recorded in the federal register of physicians—that is to say, the physicians who have been admitted to panel practice. The constitution may provide for the admission of other physicians. The association will be under the supervision of the federal minister of labor. Thus this association becomes the clearing house of the relations of the panel physicians to the *Krankenkassen*. As a result, the Hartmann league has lost its character of an independent professional league and has been transformed into a body having to do with public rights.

The Physical Aspects of Thinking, Electrical Brain Currents

In connection with every nervous and muscular activity, there are developed so-called action currents. Professor Berger, psychiatrist of Jena, has been endeavoring to prove that similar bio-electric currents occur in the cerebrum. After years of research he has secured curves from the human cerebrum, not only from the intact cranium but also through trephined areas, which show that constant electrical fluctuations are associated with the activity of the cerebrum. These bio-electrical manifestations are absent in the new born and in the infant during the first weeks of life. There is no evidence of them until the child enters the sixth week of life and not until the child is four years old does the curve attain the form that it keeps throughout the child's life. This curve Berger terms an *elektronkephalogramm*, of which there is an entirely distinct form for every person. It consists of long rather slowly moving waves (from 9 to 11 hertz per second) and short much more quickly moving waves.

This automatic cortical activity, as shown by these electric currents, continues during sleep but is interrupted during unconsciousness and in chloroform anesthesia. High long continued fever changes the *elektronkephalogramm* of every person. In mental disease associated with dementia the waves are greatly changed. Also during every type of mental work and under the influence of sensory stimuli to which the attention is directed the *elektronkephalogramm* undergoes characteristic changes. The long waves of the *elektronkephalogramm* then suddenly disappear and at the same time the shorter waves appear more distinctly. This is probably due to a blocking of the course of the automatic cortical processes. Probably this general blocking is associated with the local stimulation process in the corresponding sensory center. Berger calls this new

festation a graphic representation of the "narrowing of consciousness" as used in psychology

From the relation of the "elektrenkephalogramm" to psychic processes, Berger draws some interesting deductions

Josef Berze of Vienna divides the cortex of the cerebrum into two areas. In the external area, which comprises the first three cortical layers, the material processes that are in any wise associated with psychic activity take place. Here, according to Berze, there is no localization of definite psychic and physical performances. He terms this external layer the "intentional" sphere. Beneath it are the fourth, fifth and sixth cortical layers, which comprise the "impressionist" sphere, with strict localization. Corresponding to all psychophysical processes there are physiologic processes in the intentional sphere, and the various psychic performances are brought about through the action of this uniform psychophysical process occurring in the upper cortical layers on the material made ready by the impressionist sphere. The 'elektrenkephalogramm' is, then to be regarded as the accompanying manifestation of the uniform psychophysical activity taking place in the intentional sphere.

Open-Air Schools

The creation of open-air schools has progressed in Germany. These schools have been established chiefly for weakly children, later, forest schools for healthy children arose. Some of the hygienic advantages of the open air school, as observed and reported by the Krankenkassen, were disappearance of glandular swellings and anemia, tanning of the skin, increase of weight, increase of bodily vigor and improvement in physical appearance, lessened tendency to colds, increase of resistance and of general well being, and strengthening of the nervous system. The work in the open-air schools seeks to inculcate a fondness for a simple, natural and healthy mode of living, independence of action and self-reliance. In addition to the hygienic advantages, their importance lies, therefore, in the attainment of an education that will make for a thrifty, financially sound mode of living in family and state.

Nutrition and Mortality

Since the close of the World War, the monthly distribution of deaths in Germany and in other countries that participated in the war has undergone a change. In the spring months (February to May) the mortality curve rises far above the average, whereas in the fall months it lies correspondingly below the middle values. The mortality peak that existed before the war in December and January could be ascribed to climatic influences, and that in August, during the last decade of the previous century, was assignable to digestive disturbances in children, but the cause of the recent spring peak, according to Dr. von Hahn in addressing the medical society of Hamburg is the lack of vitamins in the diet. The vitamin theory, he pointed out, has proved two contentions beyond all doubt: (1) All forms of vitamin deficiency reduce the degree of immunity and thus increase the tendency to infection, and (2) in the German diet in spring there is a vitamin deficiency. These two experimental facts taken together furnish the reason for the spring peak in question. That nutrition is a causal factor is according to von Hahn, shown by the fact that inhabitants of the same area with different types of diet (inhabitants of agriculturally poor and agriculturally rich regions, inhabitants of sections of the cities with rich or poor residents, single persons and married persons) present widely different spring maximums of mortality, and always in the sense that the portion of the population with the diet poorer in vitamins shows a higher spring mortality. In arranging the deaths according to causes of death one finds that the spring maximum affects chiefly the infectious diseases which may be explained by the reduction in immunity, and in tuberculosis especially, in which the value of vitamins for recovery has been well established.

ITALY

(From Our Regular Correspondent)

July 31, 1933

Italian League for the Combating of Cancer

The third national convention of the Lega italiana per la lotta contro il cancro has been held in Rome, and on that occasion the new "Regina Elena" Institute erected in proximity to the Policlinico, was dedicated. The convention was presided over by Prof. Roberto Alessandri. The queen was present at the dedication.

THE CRUSADE AGAINST CANCER

The first topic, "The Organization of the Crusade Against Cancer," was presented by Prof. Arcangelo Alento, assistant director of the public health service. He discussed the limits within which prophylaxis can be effective, especially in the field of precancerous lesions, in cases of hereditary predisposition and of lesions due to occupational causes. For occupational cancers (due to tar, pitch, aniline dyes and roentgen rays), notification should be made compulsory. The organization of the crusade against cancer should be based mainly on a wide publicity campaign and on the training of medical specialists. Histopathologic research is necessary for the purposes of early diagnosis, but, owing to the difficulties it presents, it should be entrusted to well equipped university laboratories. An annual mortality of about 13,000 persons is to be regarded as the basic figure for the therapeutic organization in Italy. After surveying the work accomplished by the centers in Milan, Turin and Bologna, Professor Alento suggested that a chapter of the league be established in every province and that anti-cancer centers be created in the university cities or in the large hospitals, which would offer services for early diagnosis and surgical interventions, or application of physical agents. The two cancer institutes that are functioning at present in Italy provide in addition to the aforementioned purposes, systematic research to determine the etiology of malignant tumors and suitable methods for curative treatment.

During the discussion Professor Gaifami endorsed the need of centralization for the surgical treatment of malignant tumors. Salotti emphasized the need of centralizing the radiologic means of treatment, as they should be employed only by those who are competent. Senator Bastianelli opposed the idea of excessive specialization. He believes it would be better to increase the knowledge and the capacity of a large group of physicians and a large group of institutions in order that research may be carried on with greater facility and at a minimal expense.

PRECANCEROUS LESIONS

The second topic, "Precancerous Lesions" was developed by Professor Sotti of Rome who brought out the difficulties in endeavoring to define a 'precancerous lesion'. The histologic examination is often inadequate to establish the nature of the cancerigenic cell and must be supplemented by the biologic examination. At present it is not possible to state whether a cell or a group of cells is being transformed into cancer. Hence the term 'precancerous' does not refer to a change that is well established but to a complex of changes neither constant nor characteristic. Sometimes these changes occur in embryonal elements that have remained undifferentiated or unutilized in other manifestations there is evidence of regeneration, metaplasia, chronic inflammation or cicatricial tissues. In other cases there are signs of preceding lesions of which the cause and the nature are not easily determined. To this group belong benign tumors.

In the discussion, Fabris emphasized the frequency of primary tumors of the lung and called attention to the importance of cicatrizing inflammation of the lung as a potentially precancerous stage. Cappelli described precancerous lesions of the

skin. These lesions should be destroyed, being subjected to a radical radiologic treatment in the same manner as true cancer. Gaifami called attention to the influence of pregnancy in predisposing the cervix to cancer.

Benedetti of Bologna discussed the frequency of the transformation of gastric ulcer into cancer. He stated that duodenal cancer is rare, whereas duodenal ulcer is frequent, cancer in persons operated on for ulcer by gastro-enterostomy is very rare. Hence ulcer must not be a frequent disorder preceding cancer. Zoia, Alessandri and Morpurgo were of the same opinion.

TREATMENT OF CANCER OF TONGUE

Professors Alessandri and Busi of Rome discussed "Surgical and Radium Treatment of Cancer of Tongue." Alessandri brought out that, in order to evaluate the results of surgical treatment, it is necessary to note the extension of the lesion, the anatomopathologic and the clinical type of the tumor, and its site. In determining which are operable cases, greater care is observed than formerly, the conception of operability being confined to cases that do not widely invade the tongue and adjacent regions and that present the possibility of complete removal by the oral route (sometimes enlarged). If there are glandular metastases, they must be limited to the submental or submaxillary glands. It is well known that the two fundamental types of tumor of the tongue, the spinocellular and the basocellular, vary as to malignancy. The latter is less malignant but also less frequent than the first. A more extensive use of biopsy is to be recommended.

The results of surgical removal of cancer of the tongue are not brilliant at the best. An improvement in the results could be secured with a proper collaboration of radiology and surgery, either by removing the glands and treating the tumor with radium or by removing glands and tumors, with radium treatment before and after.

Pacetto divided cancer of the tongue into cancers with (1) surgical indications, (2) variable indications, (3) radium therapeutic indications, and (4) mixed indications. Comparing the results of treatment of Professor Alessandri's cases with those in a series of cases treated in the Curie Institute, the speaker concluded that no evident superiority of radium treatment over surgical treatment has yet been demonstrated with reference to the forms of the first and second degree, whereas for the tumors of the third and fourth degree it is advisable to combine adenectomy with radium therapy.

Professor Santoro divided radium treatment into two phases: lingual localization and localization in the lymphatic regions. For the lingual localization the technic can be said to be standardized, for almost every one employs interstitial irradiation. With reference to glandular metastasis, opinions differ. The speaker uses external radium irradiation of the lymphatic regions, employing the heaviest dose compatible with the integrity of the healthy tissues. With this technic he has treated, during the past five years, sixty patients, effecting a clinical recovery in 30 per cent.

RADIUM THERAPY IN CANCER OF THE UTERUS

Professor Bertolotti discussed the fourth topic, Radium Therapy in Cancer of Uterus. To aid in the early diagnosis of uterine cancer, it is indispensable to make more widespread the system of periodic medical examinations. Radium constitutes one of the most effective means of treating uterine cancer and in some cases gives results superior to hysterectomy. In the more advanced forms intracavitary radium therapy should be combined with roentgen therapy.

BIOLOGIC TESTS IN THE DIAGNOSIS OF CANCER

The fifth topic, Biologic Tests in the Diagnosis of Cancer, was considered by Professor Brancati of Parma who said that not one of the large number of tests in use gives absolutely

specific results. Many tests are, however, valuable, especially for neoplasms of the internal organs, and some have the advantage of ease of application. In each case the physician must coordinate in a proper manner the clinical and the biologic data, in order to formulate a true diagnosis.

LIPIDS AND TUMORS

The sixth topic, "Lipids and Tumors," was discussed by Professor Morelli of Florence, who emphasized that research on this complex subject has shown the primary importance of lipid substances in the phenomena of cellular growth in general and in neoplastic cellular growth in particular.

BUENOS AIRES

(From Our Regular Correspondent)

June 21, 1933

A Series of Lectures on the Hypophysis

Dr. Houssay, director of the Instituto de Fisiologia of the Faculty of Medicine of Buenos Aires, recently delivered a series of lectures before the Academia de Medicina of Buenos Aires. In the first lecture he spoke on the relations between the hypophysis and carbohydrate metabolism. The known functions of the anterior lobe of the hypophysis may be considered at present as belonging to four main groups: growth, sex and reproductive activities, the development and maintenance of other endocrine functions, and the metabolism of carbohydrates. The principal functions of the hypophysis are related to the metabolism of the carbohydrates, the other functions are more or less associated with it. The anterior lobe of the hypophysis contributes to the consumption of sugar, its action is antagonistic to that of insulin. Ablation of the anterior lobe of the hypophysis facilitates the hypoglycemic action of fasting and insulin and its ultimate result is the death of the animal. Hyperglycemia-producing factors have a less effective action on animals deprived of the anterior lobe of the hypophysis than on normal animals. The fact that hypoglycemic crises occur sometimes in animals deprived of the hypophysis and of the pancreas indicates that the crises are independent of insulin secretion. Not only is compensation for all the results of pituitary extirpation effected by the implantation of the anterior lobe or by the injection of its alkaline extract but even opposite effects are brought about. In toads deprived of the hypophysis and pancreas, the injection of extract of the anterior lobe of the hypophysis produces its diabetogenic action regardless of the presence or absence of telencephalon, mesencephalon, diencephalon (including the tuber cinereum), the thyroid, the sex glands, kidney, lungs and digestive tract but this action is not produced when the animals are deprived of the liver. Hypophysectomy in toads causes a decrease of the liver and muscle glycogen and of the phosphocreatinine. The animals show asthenia and sometimes convulsions and die. All the symptoms disappear and survival of the animals is assured by the implantation of the anterior lobe of the hypophysis. The implantation of the posterior lobe of the hypophysis has a less effective action. The injection of high doses of alkaline extract of the anterior lobe of the hypophysis repeated during three or four days causes hyperglycemia, glycosuria and ketonuria in normal dogs. The intravenous injection of dextrose in dogs under these conditions produces a prolonged hyperglycemic curve and the respiratory quotient increases only a little or not at all. Both normal and hypophysectomized animals injected with the alkaline extract of the anterior lobe of the hypophysis show a high resistance to insulin and present increased hyperglycemic reactions to epinephrine and morphine. All the changes characteristic of pituitary insufficiency are counterbalanced by the administration of the extract: the hypersensitivity to insulin and philorhizin disappears, the glycosuria and ketonuria pro-

duced by phlorhizin in hypophysectomized dogs increase and a condition of intense diabetes is induced in dogs simultaneously deprived of the pancreas and of the hypophysis with little or no glycosuria before the injections. The hypophysis plays a leading part in carbohydrate metabolism and is followed in importance only by the liver and the pancreas. To speak of a diabetogenic hormone is incorrect, because the production of diabetes is not a normal function of the hypophysis. Therefore it may be said that the extract of the anterior lobe of the hypophysis in high doses has a diabetogenic action and that probably the hypophysis is responsible for the hyperglycemia and glycosuria often present in cases of acromegaly. The same contra-insulin hormone is also inadequate, because its action is produced even on animals deprived of the pancreas independently of any pancreatic influence. According to Houssay, when the mass of facts studied by him and his collaborators is verified in other laboratories, it will be impossible to speak of the hypophysis without considering its metabolic role, or to consider the carbohydrate metabolism without mentioning the hypophysis.

THE HYPOPHYSIS AND THE ENDOCRINE GLANDS

In his second lecture Dr Houssay showed that hypophysectomy in dogs is followed by either lack of development or atrophy of such endocrine glands as the gonads, the thyroid, the parathyroids, the suprarenals and the thymus. The anterior lobe of the hypophysis is necessary for the development and maintenance of the endocrine glands. It is doubtful whether the hypophysis secretes a specific stimulating hormone for each gland. It is more probable that there is a general hypophyseal action, to which is added the effects of certain specific hormones. Hypophysectomy produces atrophy of the thyroid epithelium. The epithelial cells become small and flattened and have small nuclei. The thyroid alveoli are wide and their colloidal content is dense, well stainable and without vacuoles. The iodine percentage of the thyroid increases. Iodemia arises at first followed by an initial period of hyperthyroidism and then it declines. After extensive ablation of the thyroid there is no compensatory hypertrophy. The basal metabolism, as a rule, is 15 per cent below normal and it becomes 25 per cent below normal if the thyroid is removed. In dogs already deprived of the thyroid, hypophysectomy does not lower the basal metabolism. The blood plasma of dogs deprived of the hypophysis shows changes characteristic of hyperthyroidism especially an increase in the globulin content and in viscosity. The extract of the anterior lobe of the hypophysis has the same effects as the administration of thyroid (except in dogs deprived of the thyroid). It produces hypertrophy, hyperplasia and hyperfunction of the thyroid. The epithelial cells of the thyroid become enlarged, the colloidal content becomes vacuolated (it is reabsorbed), the thyroid iodine falls and the blood iodine rises, the basal metabolism rises greatly, and the pulse and the respiration increase. In the rat and guinea-pig the sensitivity to anoxemia increases (as if thyroid extract were given to them) but not if the animals are previously deprived of the thyroid. The hypophysis has an action of stimulation on the thyroid. In dogs deprived of the hypophysis as well as in those deprived of the pancreas atrophy of the parathyroid is observed in 66 per cent of the animals. These atrophic parathyroid lesions are constant and intense in dogs simultaneously deprived of both the hypophysis and the pancreas. The atrophy of the thymus, following hypophysectomy, observed in dogs by Ascoli and Legnani in 1912, and by Houssay in 1916 was also observed in rats by Smith in 1930.

RELATION BETWEEN HYPOPHYSIS AND SUPRARENALS

Dr Houssay, in the third lecture of the series June 22 discussed the relation between the hypophysis and the suprarenals. In dogs deprived of the hypophysis the weight of the supra-

renals diminishes 38 per cent of their normal weight. The atrophy occurs in the reticular zone and progresses from the inside to the outside, invading the fascicular zone. The glomerular layer is either normal or becomes hypertrophic. The atrophy is either simple or with vacuolar degeneration. The fats are more densely stained and the fat droplets are larger than normal. The medullary part is intact and the total amount of epinephrine does not vary, but because of the atrophy of the cortical layer the total amount of epinephrine per gram of weight of the gland is larger than normal. The extract of the anterior lobe of the hypophysis, on the contrary, produces a marked hypertrophy of the suprarenal cortex, the medullary part shows a slight decrease of epinephrine. In human hypopituitarism there is atrophy of the suprarenal cortex and probably suprarenal hypofunction as well. In hyperpituitarism there is hypertrophy of the suprarenal cortex.

Undulant Fever in Argentina

Investigations carried on by Dr J. M. de la Barrera at the Instituto Bacteriologico of the National Department of Hygiene of Buenos Aires showed some species of *Alcaligenes* present in Argentina. In the western region of Argentina from the Neuquen to the northern border, *Alcaligenes melitensis* is the only species found. In the goat raising regions and in the region of the littoral, *Alcaligenes suis* is the only species found. In the cattle and horse raising regions, where no goats are raised *Alcaligenes abortus* is the most commonly found species.

Marriages

- FRANK SAUNDERS HUNDLEY, Baltimore, to Miss Margaret Adreon Smith of Jarrettsville, Md., at Westminster, June 7.
ROBERT PRESTON HAWKINS, JR., Clifton Forge, Va., to Miss Grace Vernon Reynolds of University, June 9.
CHARLES FREDERICK LE COMTE, Portland Ore., to Miss Mary McNeil Darling of Milwaukee, August 12.
GEORGE M. DAWSON, West Palm Beach, Fla., to Miss Louise King of Maysville, S. C., August 26.
RUSSELL FELTS HUFFORD, Welch, W. Va., to Miss Mayme Eleanor Knight of Richmond, Va., June 17.
CHARLES HUBBARD CORNISH, Maplewood, N. J., to Miss Dorothy Elise Rand of New York, July 8.
GARLAND NORFLEET CARTER, Boynton, Va., to Miss Susan Elizabeth Carpenter of Richmond, June 24.
JOHN WESLEY HOCKER, Chattanooga, Tenn., to Miss Glenna Burke Strickland of New York, June 24.
CHARLES A. CARROLL, Manchester, Iowa, to Miss Marjorie L. Petrovitsky of Cedar Rapids, July 1.
BERNARD CANDLER GRIGSBY, Lebanon, Va., to Miss Mary Helen McKissick of Wellville, July 12.
CHARLES MARSDEN IRVIN, Roanoke, Va., to Miss Ruby Newman Hamner of Elkton, June 1.
JOHN L. WINSTEAD, to Miss Margaret Fleming, both of Greenville, N. C., September 16.
GLENN J. ANDERSON, Winterset, Iowa, to Dr. EVELYN M. OLSON of Iowa City, July 12.
FREDERICK THOMAS AMISS, to Miss Ruth Ann Broyles, both of Luray, Va., June 17.
KENNETH J. CHADWELL, Lynn, Mass., to Dr. LAURA V. TOWSE of Brighton, July 5.
EVERSON B. DAWSON, Fort Dodge, Iowa, to Miss Pauline M. Breen of Boone, July 23.
HENRY C. SAULS, Atlanta, Ga., to Miss Elizabeth Moseley of McDonough, August 19.
JOSEPH E. DVORAK, to Miss Louise Radschlag, both of Sioux City, Iowa, July 1.
JOE FRANK ADCOCK, to Mrs. Annette Haney, both of Sanatorium, Texas, recently.
EDGAR E. DUNCAN, to Miss Carolyn Barron, both of Seattle, September 9.

Deaths

Arthur Mills Corwin * Chicago, Rush Medical College Chicago 1890, at one time demonstrator of physical diagnosis at his alma mater and professor of physical diagnosis, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, associate professor of otology and rhinology and laryngology Chicago College of Medicine and Surgery and the Bennett Medical College fellow of the American College of Surgeons, aged 69 on the staffs of the Chicago Eye, Ear, Nose and Throat Hospital and the West Suburban Hospital, Oak Park, Ill, where he died, September 9, of chronic nephritis, uremia and myocarditis

John Francis Ranken * Brooklyn, New York Homeopathic Medical College and Hospital, 1901 fellow of the American College of Surgeons, at one time adjunct professor of surgery, New York Medical College and Hospital for Women served during the World War, aged 58, on the staffs of the Jamaica Hospital, Richmond Hill, Huntington (N Y) Hospital Brooklyn Nursery and Infants' Hospital, Cumberland Hospital and the Carson C Peck Memorial Hospital, where he died, September 16 of heart disease

Karl Ohnesorg * Medical Inspector, Commander U S Navy, Carmel Calif, University of Pennsylvania School of Medicine, Philadelphia 1895 entered the navy in 1900 and retired in 1922 for incapacity resulting from an incident of service, fellow of the American College of Surgeons, aged 59, died, May 11 in the U S Naval Hospital Mare Island, of arteriosclerosis and ethmoidal sinusitis

Eugene Bruce Eastman * Portsmouth N H McGill University Faculty of Medicine, Montreal Que, Canada, 1902 member of the Massachusetts Medical Society and the New England Surgical Society fellow of the American College of Surgeons, for many years on the staff of the Portsmouth Hospital, aged 56 died September 6, of hypertensive heart disease and chronic nephritis

Fletcher Reese Harris, Henderson N C, University of Virginia Department of Medicine Charlottesville 1881, an Affiliate Fellow of the American Medical Association, past president of the Vance County Medical Society, county health officer, at one time member of the state board of health, aged 73, died, August 27, of chronic nephritis.

Richard W Jones * Wausau Wis Northwestern University Medical School, Chicago 1902 fellow of the American College of Surgeons veteran of the Spanish-American and World wars, aged 54, on the staffs of the Wausau Memorial Hospital and St Mary's Hospital, where he died, August 17, while performing an operation

James Dawkins Cromer, Atlanta Ga, University of Nashville (Tenn) Medical Department 1894, member of the Medical Association of Georgia, veteran of the Spanish-American and World wars, aged 65 died August 31, in the Emory University Hospital of coronary occlusion

Louis O Nordstrom * Salina, Kan College of Physicians and Surgeons Medical Department Kansas City University, 1902, president and formerly secretary of the Saline County Medical Society, on the staff of St John's Hospital, aged 57, died May 28, of septicemia

George M Preston * Lynchburg, Va University of Virginia Department of Medicine Charlottesville 1878 fellow of the American College of Surgeons president of the staff of the Marshall Lodge Memorial Hospital aged 77 died, July 3, of angina pectoris

James Locke Perkins * Cranford N J Yale University School of Medicine New Haven Conn 1898 fellow of the American College of Surgeons, aged 56 on the staff of St Elizabeth's Hospital Elizabeth where he died August 15 of carcinoma of the stomach

John M Manning, Durham N C Bellevue Hospital Medical College New York 1882 member of the Medical Society of the State of North Carolina for many years mayor of Durham aged 76 died August 30 in Chapel Hill of chronic nephritis

Robert Wales Prentiss, Middlebury Vt Baltimore Medical College 1901 member of the Vermont State Medical Society on the staff of the Porter Memorial Hospital aged 61, died May 30 of chronic myocarditis and acute dilatation of the heart

Luther M Holloway, Salona, Pa, Bellevue Hospital Medical College New York, 1868, member of the Medical Society of the State of Pennsylvania Civil War veteran, aged 88 was found dead August 7 of angina pectoris

Phineas A Renie, Union Ill Hahnemann Medical College and Hospital, Chicago 1891 member of the Illinois State Medical Society, aged 66, died August 18, as the result of injuries received in a fall several weeks ago

Frank Chiles, Honey Grove Texas, Louisville (Ky) Medical College, 1903 member of the State Medical Association of Texas aged 55 died suddenly, June 26, of heart disease while on a vacation trip near Antlers, Okla

Morton Marcellus Kent * Trenton, N J Medico-Chirurgical College of Philadelphia 1901 aged 53 medical director of the Chambersburg General Hospital, where he died August 23, of carcinoma of the intestine

S Rowland Hill, Lansing Mich, Michigan College of Medicine and Surgery, Detroit 1905, for many years health officer of Lansing aged 56, died, August 28, in the Receiving Hospital, Detroit, of heart disease

John W Leckie, Hamburg Pa, Hahnemann Medical College and Hospital of Philadelphia 1893 on the staff of the Hamburg State Sanatorium for Tuberculosis, aged 64, died, August 10, of cerebral thrombosis

Howard S Reeser, Reading Pa Jefferson Medical College of Philadelphia 1867 member of the Medical Society of the State of Pennsylvania, Civil War veteran, aged 87, died, August 12, of cerebral embolism

John William Rush, Bloomington, Texas Vanderbilt University School of Medicine, Nashville Tenn 1884 member of the State Medical Association of Texas, aged 74, died suddenly, July 18 of heart disease

Walter Ennis Hays * Sterling Colo Albany (N Y) Medical College, 1905, on the staff of St Benedict Hospital, aged 53, died July 3, in the Mercy Hospital, Denver, of empyema and lobar pneumonia

Theodore F Blanke, Garden City, Kan Homeopathic Medical College of Missouri, St Louis, 1889, member of the Kansas Medical Society, aged 72, died, May 11, in Joplin Mo of carcinoma of the face

Walter Peter MacGibbon, New York, Hahnemann Medical College and Hospital, Chicago 1898 aged 61 died August 6 in the New York Homeopathic Medical College and Flower Hospital, of a skull fracture

George Gurnee Esley, Sodus N Y, University of Rochester (N Y) School of Medicine, 1931, member of the Medical Society of the State of New York, aged 30, died, August 1, in an automobile accident

Solomon L Zeltner, Chicago Rush Medical College Chicago, 1895, member of the Illinois State Medical Society aged 71, on the staff of St Mary of Nazareth, where he died, August 11, of heart block

Lauren Clay Thomas, Latrobe Pa College of Physicians and Surgeons Baltimore 1887 aged 73, died June 16 in the Johns Hopkins Hospital, Baltimore, of cerebral hemorrhage and chronic nephritis

Thomas Omar McSwain, Visalia, Calif College of Physicians and Surgeons of San Francisco 1899 member of the California Medical Association aged 71 died August 10, of cerebral hemorrhage

Joseph Charles Hormisdas Lortie, Ludlow, Mass School of Medicine and Surgery of Montreal, Que Canada 1892 aged 64, died, July 27, in the Mercy Hospital, Springfield, of uremia

Herman Evant Jones, Roanoke, Va, University of Virginia Department of Medicine Charlottesville 1886 aged 72 died August 17, in a local hospital of acute hepatitis and nephritis

Henry Clyde Telford, Ottawa Ill University of Michigan Homeopathic Medical School Ann Arbor 1905 aged 61 died June 22 in the Ryburn Hospital, of peritonitis and ruptured appendix

William Henry Emmons, Decorah Iowa Rush Medical College Chicago 1892 member of the Iowa State Medical Society, aged 65 died September 9 of coronary thrombosis

Thomas D McGlasson, Winslow Ind Louisville (Ky) Medical College 1884 for many years bank president aged 73 was found dead in bed August 16 of cerebral thrombosis

Wilson James Perry Billings, Mont Rush Medical College Chicago 1905 member of the Medical Association of Montana aged 56 died August 10 of myocarditis

Ira Clinton Somers, Chanute, Kan., University of the South Medical Department, Sevanee, Tenn., 1901, aged 76, died, July 7, of malignancy of the urinary bladder

Buford Kirkman Parrish @ Mansfield, La., Tulane University of Louisiana School of Medicine, New Orleans, 1916, aged 47, died, August 25, of subdural hemorrhage

Julius Buzik @ Chicago, Universitat Basel Medizinische Fakultät, Basel, Switzerland, 1915, aged 72, died, May 26, of coronary thrombosis and chronic myocarditis

Ernest H. Montcalm, New York, University of the City of New York Medical Department, 1892, aged 63, died, August 5, of coronary sclerosis and thrombosis

Thomas J. Wilson, Pomona, Calif., Memphis (Tenn.) Hospital Medical College 1887, aged 76, died, July 12, of chronic myocarditis and tuberculous peritonitis

Harold L. Lown, Lansing, Mich., University of Michigan Homeopathic Medical School Ann Arbor, 1904, aged 55, died, July 28, of hypertrophic cirrhosis of the liver

Horace G. Wootten, Clarksville, Texas, Dallas Medical College, 1904, aged 60, died May 6, in the Baylor Hospital, Dallas, of pneumonia, following an operation

John Joseph Carroll @ San Francisco John A. Creighton Medical College, Omaha, 1919, aged 37, died, July 21, in the Mary's Help Hospital, of cerebral sclerosis

John L. Ingram, St. Louis American Medical College St. Louis, 1884, Barnes Medical College, St. Louis, 1900, aged 72, died, August 15, of heart disease

Charles Clinton Ogle, Chambersburg Pa. Hahnemann Medical College and Hospital of Philadelphia, 1905, aged 59, died, May 19, of arteriosclerosis

Alexander B. McTeer, Rockford, Tenn., University of Tennessee Medical Department, Nashville, 1884, aged 76, died August 12, of heart disease

George W. Law, Grand Rapids, Mich. Michigan College of Medicine, Detroit 1882, aged 81, died suddenly, September 1, of heart disease

William Whipple McCormick, Spokane, Wash. Gross Medical College Denver, 1888, aged 68, died, July 12, of a cerebral hemorrhage

John A. Whiting, Los Angeles, Detroit College of Medicine, 1887, aged 71, died, July 3, of chronic myocarditis and bronchopneumonia

Alvin McClung, Beverly W. Va., College of Physicians and Surgeons, Baltimore, 1915, aged 43, died, May 13, of cardiac infarction

Robert Putnam, Brinkhaven, Ohio, University of Wooster Medical Department, Cleveland, 1872, aged 81, died, August 10, of prostatitis

John O. Taft @ Minneapolis, Medical Department of Hamline University Minneapolis, 1907, aged 54, died, August 29, of heart disease

J. Clinton Maxfield, Hettick, Ill. St. Louis College of Physicians and Surgeons, 1891, aged 72, died, August 12, of cardiac asthma

John Claude Potter @ Framingham, Mass., Baltimore Medical College, 1905, aged 54, died suddenly, July 30, of heart disease

Delbert L. Rose, Empire, Mich., Barnes Medical College, St. Louis, 1899, aged 59, died, September 1, of carcinoma of the prostate

Adolph H. Schonger, North Branch, N. Y., Pulte Medical College, Cincinnati, 1887, aged 70, died, May 27, of cerebral hemorrhage

Alden J. Woodruff, Watertown, N. Y., New York Homeopathic Medical College 1885, aged 83, died July 6, of arteriosclerosis

Patrick George Alldredge, Fort Sumner N. M. Atlanta (Ga.) Medical College, 1875, aged 80, died, July 16, of angina pectoris

Myron Cory Lyons, Winnetka, Ill. New York University Medical College, 1896, aged 73, died, August 13, of heart disease

Boyd Cornick @ San Angelo, Texas Hospital College of Medicine, Louisville, 1877, aged 77, died, July 4, of heart disease

Thomas W. Myers, Wichita, Kan., University Medical College of Kansas City, 1904, aged 53, died July 14

Luther Mathis, Fairview, Okla., Barnes Medical College, St. Louis, 1899, aged 61, died, July 19

Bureau of Investigation

THE "MODERN INSTITUTE" FRAUD

Another Quack Obesity Cure Debarred from the Mails

The Modern Institute, 381 Fourth Avenue, New York City, was incorporated in the fall of 1931 under the laws of the State of New York, with Charles G. Sinclair, president, and Miss Zita Leary, secretary and treasurer. The business consisted in selling through the United States mails a so-called Triple Action System for reducing persons suffering from obesity. Victims were obtained through advertisements published in magazines. A typical advertisement read in part:

LOSE FAT THREE TIMES AS FAST! Amazing New Triple Action System is GUARANTEED to Reduce You—as much as you want, wherever you want. NOW watch that fat vanish! See it fade away like magic. Now actually get rid of that excess weight. Take off as much as you please—in one third the time! You'll be slim before you know it! This amazing new way. You'll lose five to ten pounds almost overnight!

Combines THREE Famous Fat Reducers. Why waste time struggling to lose a few pounds when the amazing super system fairly makes excess fat melt away, with almost no effort on your part? Just use these three harmless, healthful preparations, follow simple directions and watch yourself grow slim!"

The three preparations referred to in the advertisement were further described as (1) "Triple-X Saline Salts," (2) "Triple-X Venus Cream," and (3) "Triple-X Baths." The obese public was urged to send \$1.95 for the "special introductory" treatment. Those who sent the money received a small package containing two cylindrical paper boxes about an inch and a half in diameter and four inches long, and a very small collapsible tube. One of the boxes contained the so-called Triple-X Saline Salts, the other the Triple-X Bath Tablets, while the collapsible tube held the Triple-X Venus Cream.

When these preparations were analyzed by chemists in the Food and Drug Administration of the Department of Agriculture, the Triple-X Saline Salts were found to contain tartaric and citric acids, soda, epsom salt and Rochelle salts. The Triple-X Bath Salts contained tartaric acid, soda and potassium phosphate. The Venus Cream was merely a vanishing cream with the odor of camphor.

The directions were to put one-half teaspoonful of the Triple-X Saline Salts in a glass of hot water which was to be drunk before breakfast. One of the Triple-X Bath Tablets was to be put in a bathtub containing water as hot as the victim could bear it, in which she was to remain fifteen minutes. The Triple-X Venus Cream was to be used as a massage cream.

The amount of material sent for \$1.95 was ridiculously small and shortly after the victim received it she got a circular letter explaining that she could not expect very much reduction from the small amount of material obtained in the introductory treatment. The main thing was to "keep up the treatment faithfully." The poor stylish stout was told "You must go on, for real, everlasting slimness is just around the corner." One would have thought that the phrase "just around the corner" would have been enough to arouse serious doubts of the efficacy of the treatment in the minds of those who have been through the economic depression. But apparently the suggestion that one should purchase "the complete, advanced course of treatment," containing a "giant-size supply" of the three preparations already mentioned, was followed by many, and eight dollars additional was sent in for more of the trash. The letter wheedling this money out of the victims was signed "Florence Kingsley," and subsequent follow-up circular matter was sent in an endeavor to induce a further purchase, the last letter of the series being what purported to be handwritten personal letter from the real or mythical Florence Kingsley herself.

While the advertisements told the prospective purchaser that the "system" made the "excess fat melt away with almost no effort on your part," the victim was told—after parting with her money—that she should take various exercises, many of which, according to expert medical testimony submitted by the government, would be dangerous to a great many people suffering from obesity. She was also urged to follow certain diets.

The whole thing was an obvious and patent swindle but it was necessary under the law for the government to go to con-

siderable trouble and expense in introducing medical testimony to prove that it was a swindle. On July 24 Judge Horace J. Donnelly, Acting Solicitor for the Post Office Department, recommended the issuance of a fraud order closing the mails to the Modern Institute, Inc., Modern Institute and Florence Kingsley. Postmaster-General Farley issued such an order on the same date.

Correspondence

ROCKY MOUNTAIN SPOTTED FEVER

To the Editor—The following quotation is from an editorial on Rocky Mountain spotted fever which appeared in *THE JOURNAL*, August 19. The following comments are made as a reply to the statements made in the editorial:

A much neglected phase of this problem has been revived by the work of Zinsser and Ruiz Castaneda on Mexican typhus, a disease that seems quite closely related to Rocky Mountain spotted fever. These workers produced a highly protective serum for the guinea pig by immunizing a horse to a phenolized suspension of *Rickettsia* obtained from infected rats previously irradiated with γ rays.

The early immune serum studies of Ricketts and Gomez and of Hememann and Moore and the later ones of Noguchi are then referred to, and the editorial goes on as follows:

Despite these encouraging experimental results there has been no further report of an attempt to increase the potency of immune serum against Rocky Mountain spotted fever and there has been no recorded example of the use of the serum in the prophylaxis and treatment of the disease in man. This is indeed surprising in view of the need of such a serum. An immune serum would be of unquestioned value as a prophylactic measure in persons who have been bitten in localities known to harbor ticks infected with highly virulent strains of *Rickettsia*. It would be especially indicated in those cases in which the ticks have been found attached in an engorged state since it has been shown by Spencer and Parker that infection is most likely to occur after the tick has remained attached to the host for a number of hours and allowed to engorge fully. In light of the available experimental data the use of the serum in the treatment of the disease is still of doubtful value. However since the serum is known to possess definite neutralizing powers beneficial results may probably be obtained if the serum is administered very early in the course of the disease in man. Further investigations on this phase of the problem are much needed.

As regards published data concerning serum prophylaxis and serum therapy of Rocky Mountain spotted fever the writer of the editorial was justified in his use of the phrase describing serum prophylaxis as "a much neglected phase of this problem." As a matter of fact however, considerable experimental work along the line indicated has been performed at the Hamilton Laboratory and elsewhere the past decade.

In case of an impending infection, the probable value of the prophylactic use of convalescent serum or of hyperimmune rabbit serum, such as that of Noguchi has been recognized for many years. It has however been felt that except under unusual conditions, there is very little field for its use. Most persons who are exposed to possible infection by tick bite are bitten so frequently that the use of such a serum is not practical on account of the relatively short duration of the passive protection conferred and the consequent need of repeated serum injections. At one time it was thought that such serum would be of considerable value to laboratory workers. This has not proved true at Hamilton, however. Most of those who are engaged in spotted fever research work make use of the Public Health Service preventive vaccine and furthermore most laboratory infections have been acquired without any suspicion of the fact on the part of the person concerned. There is a possible limited use for such serum among persons who are bitten by ticks at rare intervals but since the chance of infection is usually less than and seldom greater than one in fifty it would be only the occasional person who would become sufficiently alarmed to desire a protective injection of serum.

Regarding serum therapy both Surgeon R. R. Spencer working at the National Institute of Health and Noguchi at the

Rockefeller Institute were unable to produce a horse serum of definite value. Their results were never published. The most interesting experimental results at the Hamilton Laboratory have been secured with serums from goats that have been injected with repeated large quantities of highly potent tick virus—a much more potent inoculum than the blood virus used by Ricketts and his associates and by Noguchi. In connection with these studies, a herd of more than twenty goats is being maintained at this laboratory. Occasional goats produce a serum of sufficient potency that 1 cc given on the first or second day of fever will insure 100 per cent recovery among guinea-pigs and monkeys. There is a marked lessening of the degree of scrotal involvement but a less evident effect on the thermal curve. In one such series of tests of more than 400 treated guinea-pigs and two monkeys, all recovered, while all control animals died. The results have not been consistent however. A serum to be of practical value for treatment must not only be sufficiently potent to be effective when administered in a reasonable quantity but also must have definite therapeutic value when given on at least the third or fourth day after onset. The latter point is essential, since in the Rocky Mountain region at least, the majority of patients do not report for treatment until they have been ill for several days. Experimental attempts to produce and concentrate a therapeutic serum constitute one of the main phases of the research work at this laboratory at the present time and is being pushed as fast as is permitted by the necessary curtailment of government expenditures.

Convalescent serum has been repeatedly used by local physicians in the treatment of the highly fatal type of the disease that prevails in parts of western Montana and certain other sections of the Rocky Mountain region. It has perhaps been most extensively tried out by Dr. Herbert Hayward of Hamilton, special consultant of the service. There have been no results of value, except perhaps in a single instance when the blood employed was transfused from a patient recovered less than two weeks. Blood from the same donor subsequently failed to affect the course of infection in several patients favorably, and in at least one instance it was very possible that the administration was deleterious.

TOXICITY OF DINITROPHENOL

To the Editor—It was to be expected following the article on the 'Actions and Uses of Dinitrophenol' by Drs. Cutting, Mehrtens and Tainter (*THE JOURNAL*, July 15) and general newspaper and magazine comment throughout the country, that it would attract a great deal of public interest and inquiry as to its therapeutic application.

A university professor who is much overweight and who had been on a great many reducing diets with indifferent results, consulted me with the purpose in mind of using this drug. The dangers of the drug were pointed out to him and he read the article in *THE JOURNAL* and the editorial comment in the same issue carefully but still evinced a strong desire to use this substance. He stated that he realized the possibility of body damage and our present incomplete knowledge of the pharmacology of the drug but in a spirit of heroism () he was willing to offer his body as an experiment to medical science. And so we proceeded with the use of this dye. He weighed 263 pounds (119 kg.) is 6 feet (183 cm.) tall and his age is 39. He was given 3 mg. per kilogram of body weight daily in the form of a capsule. He was told to report to me daily as to the effect of the drug on temperature, pulse rate, presence or absence of sweating, nervousness and its effect on his appetite. Until three days had elapsed no ill to

ward symptoms had arisen. On the fourth day he complained of a feeling of heat, he perspired profusely, he complained of pain in the buttocks and down the legs, he felt fatigued toward the end of the day, his appetite had increased, and he had an uncomfortable feeling in the abdomen. Examination revealed injected conjunctiva, with a definite icteric tint to the eyeballs. Beads of perspiration were on his forehead, his pulse rate had increased from 60 to 90, there was a lowering of blood pressure from 125 systolic to 112 systolic, his abdomen was sensitive, particularly over the liver area, the urine showed a trace of bile and a slight trace of sugar. He was advised to stop the use of the drug immediately and four days later when he was reexamined he was feeling well again. The icterus had disappeared, the pulse rate was normal, there was no more excessive sweating, and the pain in the buttocks and abdomen had disappeared.

I am writing this communication because it is of interest that, despite the warnings issued by the authors in their article and an editorial comment along the same lines, there will no doubt be a good many people and doctors who will be tempted to use this drug. This is undoubtedly an example of liver damage arising in an individual after use of the drug in minimal doses, after four days. Incidentally, there was some loss of weight but not enough to compensate for the possible harm that it might have done this person.

HENRY H. HART, M.D., Syracuse, N. Y.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF ITCHING IN RINGWORM OF TOES

To the Editor—1 Kindly give me any suggestion you can offer on a stubborn case I have under my care. A young white woman has a constant annoying itching on the side and undersurface of the third toe of the right foot. The only condition that is visible is the appearance of small vesicles under the skin. This condition is terrifying and is present during the entire hot weather. When the vesicles rupture the surface is raw. Constant rubbing to the stage of acute irritation will relieve the itching for a short while. The physical examination of the patient is negative. The Wassermann reaction is negative. She is a blonde and has a sensitive skin. I have tried various local soothing and stimulating preparations and ultraviolet rays. Nothing has given satisfactory results. 2 I want to ask your advice about my case. I have an annoying itching between my toes at times summer and winter. My condition is relieved by constant rubbing to the stage of acute irritation. I am in the best of health and am 34 years old. My physical examination is negative. The Wassermann reaction is negative. My skin is fairly sensitive. I have tried numerous local soothing and stimulating applications and ultraviolet rays without success. Please omit name and address.

M.D. South Carolina

ANSWER—1 This is most likely a ringworm infection or a case of localized sensitization. In the first case, the roofs of the vesicles laid upside down on the slide and soaked in 10 per cent sodium hydroxide solution for from one to seventy-two hours will possibly show the fungi. If they are found, a weak alcoholic solution of iodine may be painted on once daily. From 3 to 5 per cent should be strong enough. After the vesicles have ceased appearing the iodine should be applied every other day later once a week, some treatment being continued for months after apparent cure. A 1 per cent aqueous solution of potassium permanganate may be used in place of the iodine, changing to an ointment when the permanganate has caused uncomfortable dryness. Weak Whitfield ointment, 3 per cent salicylic acid and 6 per cent benzoic acid in ointment of rose water or ointment of ammoniated mercury may be used. The latter should never be used in connection with iodine treatment.

If the eruption is due to sensitization, protection from soap and water using a 0.5 per cent salicylic acid alcohol wash followed by zinc paste thinly applied should help. Crude coal tar ointment, 6 per cent each of crude coal tar and zinc oxide in petrolatum, often is of value thinly applied.

2 Is there in connection with the itching, maceration of the skin between the toes? If so, this also is ringworm and

Whitfield ointment will probably relieve it. The fungus may be found in the macerated skin. Otherwise it may be local pruritus, and a fairly strong camphor or camphor and menthol ointment or compound resorcinol ointment may relieve it, at least temporarily.

HYPERESTHESIA OF RIGHT HAND AND FOOT

To the Editor—A man aged 56 complains of numbness and a prickling feeling (as when one hits the crazy bone) limited to the thumb and fingers of the right hand and to the right foot from the mid-dorsum to the toes. It has lasted two months. The onset was sudden while the patient was working. These sensations are constant but are more intense in the early morning, especially when he touches some object. The past history is essentially negative except that he had rheumatism twenty-eight years ago in both feet but has been free from any such symptoms since. Physical examination is absolutely negative except that the blood pressure is 170 systolic 98 diastolic. The teeth show lack of care. The reflexes are normal, the proprioceptive and epieric sensations are normal, sensations of touch, heat and cold are also normal. He states that in grasping an object he cannot always tell how tight he is holding it and if he is not careful he is apt to drop it. Laboratory results seem to be normal: red blood cells 4,600,000; hemoglobin 91 per cent; red blood cells apparently normal in size and shape; white blood cells 5,200; polymorphonuclears 74 per cent; lymphocytes 26 per cent. Routine analysis is absolutely negative. The Wassermann reaction is negative. The patient is a tinter by trade and has worked at this profession for seven years. In his work he comes in contact indirectly with the following pigments: lead chromate, zinc oxide, titanium dioxide, zinc sulphide, iron ferrocyanide, ultramarine blue, iron oxide and lead sulphate. He uses the following solvents: xylene, amyl acetate, toluene, butanol and ethyl acetate. The last is really the only solvent he comes in direct contact with. His job is to mix the pigments with the solvents in nitrocellulose cotton and match tints. This condition is a constant source of worry and irritation to him and I wish to ask your help in diagnosis and treatment of this case. The facts set forth are meager but that is all there is. Any suggestions on your part as to history or laboratory tests will be carried out. Please omit name and address.

M.D. Kansas

ANSWER—The sudden onset and simultaneous appearance of the disability in the hand and in the foot of the same side suggest that the seat of the lesion is in the brain rather than in the extremities. The described uncertainty in holding objects would indicate involvement of the sensory rather than the motor pathways, testing the patient's ability to count rapidly applied stimuli, to recognize as separate stimuli two simultaneously applied points of a compass and to appreciate numerals traced on the affected hand or foot may disclose impairment in sensation when the more usual methods of testing sensation fail.

The sudden onset, the age of the patient and the hypertension are presumptive evidence that the lesion has a vascular basis. The exact nature of these lesions usually remains in doubt. Presumably there is no disease elsewhere, as in the heart, that might furnish the source of an embolus, and presumably also poisoning with lead has been eliminated as far as this can be done. Most of the poisons affecting the nervous system select the peripheral nerves and tend to be diffuse in their action.

It would be advisable to examine the spinal fluid to make roentgenograms of the head and to check the optic fundi from time to time. Tumors of the brain occasionally announce themselves in an apoplectic form.

The short duration of the disability leaves the prognosis in doubt but, generally speaking, improvement may be anticipated.

Really effective treatment for such conditions is not included in the modern advances of medicine and for want of anything better, physicians still pay homage to the clinicians of the past by prescribing salicylates and iodides. The patient's daily work supplies the necessary physical therapy. Adjustment of any emotional stresses is indicated and a period of physical rest each noon should be advised.

TEST FOR URINARY DIASTASE

To the Editor—In *Surgery, Gynecology and Obstetrics* for July 1933 the test for urinary diastase is referred to and I shall appreciate your publishing a description of this test. It is mentioned twice in the summary of an article on acute pancreatitis on pages 20-22 of the *International Abstract of Surgery*. A. E. CLARK, M.D., Monterey Park, Calif.

ANSWER—Wohlgemuth in 1908 discovered a diastatic ferment in the urine and described a method for its determination. The amount of diastase is given by the number of cubic centimeters of a 0.1 per cent starch solution digested by 1 cc. of fresh urine. Normally the diastatic index is between 65 and 30. The presence in the urine is due to the absorption of diastase from the alimentary tract into the blood stream and its excretion by the kidneys.

The original method has been modified by several investigators, notably by E. C. Dodds (*Brit J Exper Path* 3:136 [June] 1922), who found that the result varies with the hydrogen

ion concentration of the urine. Each enzyme has its optimum pH , and for urinary diastase this value is 6.1. Ammoniacal decomposition, making the urine more alkaline, decreases the diastatic power by the Wohlgemuth method but not by the Dodds modification. It is also important to know that diastase clings to urinary deposits and hence the urine should be well shaken before testing.

In renal disease the diastase of the urine may be decreased. In acute pancreatitis or in so-called fat necrosis of the pancreas the diastase is usually markedly increased, rising to 100-200 or even higher. It is in this disease that the urinary diastase test finds its greatest value. In chronic pancreatitis the diastase may or may not be raised.

The technique of the test as modified by Dodds is as follows. A 0.2 per cent solution is freshly prepared. To 15 cc of urine, 6 cc of a phosphate buffer solution is added. This solution is made thus: Solution A is made by dissolving 11.876 Gm of $NaHPO_4 \cdot 2H_2O$ in 1 liter of boiled distilled water; the solution being kept in a paraffin-coated bottle. Solution B is made by dissolving 9.078 Gm of KH_2PO_4 in 1 liter of boiled distilled water and is stored in a paraffin-coated bottle. Fifteen cc of solution A is added to 85 cc of solution B. The mixture should have a pH of 6.1.

After the 15 cc of urine has been mixed with the 6 cc of buffer solution, a series of twelve test tubes one-half by 4 inches in size is set up. First buffered urine in decreasing amounts from 15 cc down to 0.05 cc is added, then distilled water to make 2 cc in each tube. Lastly and rapidly, 1 cc of 0.2 per cent fresh starch solution is added to each tube. The tubes are incubated for thirty minutes at 37°C, cooled, and a few drops of fiftieth normal iodine is added to each tube. The tube that just loses the mauve tint of the iodine is the one in which the starch was just digested. The calculation is then made of the amount of undiluted urine in this tube. For instance if 0.5 cc of diluted urine was required this equals 0.1 cc of undiluted urine. This amount digested 1 cc of 0.2 per cent starch or 2 cc of 0.1 per cent starch. The number of Wohlgemuth units is given by the number of cubic centimeters of 0.1 per cent starch digested by 1 cc of urine in the foregoing instance—20 units of diastase.

Cohen and Dodds have devised a colorimetric method which gives the exact number of units present (*Brit M J* 1:618 [April 5] 1924).

THROMBOSIS AFTER INJECTION TREATMENT OF HEMORRHOIDS

To the Editor—I am writing to ask whether from your experience or knowledge or information available from any source you are able to inform me as to whether there is any danger of causing thrombosis if when injecting hemorrhoids with such mild solutions as 5 per cent phenol (carbolic acid) or 4 or 5 per cent quinine and urea the solution should go directly into the hemorrhoidal veins. I have used the solutions in treating internal hemorrhoids for the last eleven years having treated nearly 900 private cases in that time. There have never been any bad results although I am sure that in many cases the injection was into the veins and that in these cases the quickest and best results were secured in getting rid of the hemorrhoids. The reason I ask this question is that the author of one of the textbooks on proctology states that when he took up the work he was shown how to avoid the veins in making the injection, although he does not know as there would be any harm done if the solution (or some of it) did go directly into the veins. Another reason is that the use of quinine hydrochloride and ethyl carbamate in the injection of varicose veins of the legs involves some danger of phlebitis by a clot forming and lodging in a vein some distance from the section being treated. I had this occur once causing a mild phlebitis. This danger and the tendency to cause sloughing if some of the solution gets into the tissue surrounding the vein has caused me to change to the use of other solutions when injecting varicose veins of the legs. In the standard solution of quinine hydrochloride and ethyl carbamate used in the treatment of the veins there is about three times as much of the quinine as there is in the 4 per cent solution of quinine and urea hydrochloride that I make up for use in treating hemorrhoids. I do not know but that the difference is even greater than this. Whether the difference in the strength of the solutions would make one more apt to cause trouble than the other I am anxious to learn. I have never had any untoward results in using the solution in the treatment of hemorrhoids except in one case in which a patient had an intolerance for quinine in any form. My experience in treating hemorrhoids has convinced me that when the solution that I use goes directly into the veins the reaction is so slight as to be unnoticeable and the hemorrhoids disappear and recovery takes place within three days instead of anywhere from a week to three weeks.

T. F. McNAMARA, M.D., Rochester, N. Y.

ANSWER—It has been shown by experimental study that hemorrhoids which have been injected with 5 per cent phenol or 5 per cent quinine and urea hydrochloride have a thrombosis of at least some of the vessels. In fact in the vascular type of hemorrhoids this is the chief factor in their cure by the injection method. There seems to be little objection to a small amount of solution getting into the vessels nor are instances recorded of ill effects arising from it. Occasionally a patient complains of a bitter taste in the mouth immediately after a hemor-

rhoid has been injected with quinine and urea hydrochloride. The size and character of the hemorrhoidal vessels are such that the probability of phlebitis occurring from a dislodged clot is not as great as in the large veins of the leg such as are injected for a varicose condition. Any clot dislodged from a hemorrhoidal vessel must of necessity be small, but serious complications might arise in case the clot that was loosened became infected. Liver abscess has always been a bogey-man brought forth by those opposed to the injection method. Only one case has been reported (about ten years ago in *THE JOURNAL*). In a series of some 50,000 individual injections for internal hemorrhoids, complications have included slough, secondary hemorrhage, marginal abscess and quinine intolerance but not a single death. There is always some thrombosis of the vessels and cure is probably accomplished and fewer injections are necessary when the thrombosis is relatively extensive.

PREPARATION OF CADAVERS FOR DISSECTION IN TROPICAL COUNTRIES

To the Editor—I shall appreciate if you will kindly give me the best formula for preparing corpses for the teaching of anatomy also your opinion about the Kaiserling formula. I am going to live in the tropics and the climatic conditions there corrupt the cadavers very quickly.

CARLOS LEIVA, M.D., San Salvador, Central America

ANSWER—The blood should be washed out of the blood vessels if practicable, an hour or two after death. This is usually impracticable.

Into one femoral artery by a three-way cannula, equal parts of phenol U.S.P., glycerin and alcohol should be injected. 6 liters to each 150 pounds (68 Kg). The injection should be done slowly by gravity pressure of 3½ or 4 feet for several hours (over night). Should any arteries be completely blocked through disease or impassable blood clots the parts supplied by them can easily be distinguished from the parts into which the fluid has passed. Such parts may be further treated by the injection with a large hypodermic needle of a considerable amount of this preserving fluid directly into the tissues in several places. The femoral artery should be tied above and below the point of injection and about two days should be allowed for the fluid to penetrate the tissues thoroughly.

To inject arteries with a color mass (Souichon's method) a mixture should be used consisting of crimson aniline solution 45 cc, potassium antimony tartrate solution 12 cc, corn starch (put through a sieve), 1 Kg, hot (not boiling) water, 1 liter. The corn starch and water are rubbed up in a mortar to make a thick cream. The crimson aniline solution is added and then the potassium antimony tartrate. The latter is to prevent the diffusion of the color mass through the walls of the smaller arteries. Force should not be used in injecting the color. It should be allowed to remain in the vessels for fifteen minutes and any excess permitted to run out freely.

Crimson aniline solution consists of crimson aniline crystals, 30 Gm, alcohol 30 cc, water 1 liter.

Potassium antimony tartrate solution is made by dissolving 4 Gm of potassium antimony tartrate in 125 cc of water.

After the color solution has been in the arteries for twenty-four hours, it sets.

Cadavers may then be stored by immersion in tanks containing 3 per cent phenol in water. In this solution they will keep indefinitely even in the tropics.

Kaiserling's fluid is useful for the preservation in something like natural colors of museum preparations. Tumors and organs may be so preserved but not entire human bodies.

TOXICITY OF BENZINE AND WOOD ALCOHOL USED IN SHOE INDUSTRY

To the Editor—Kindly give me information on the following point. In our shoe factory those workmen who are cleaning white shoes are made sick in from one to three weeks by the fluid used to clean white shoes. This fluid is a combination of wood alcohol, benzene, ether and possibly some other petroleum product. Can the workman take any precautions to avoid this illness which is a combination of one or more of the following symptoms: nausea, vomiting (often severe), headache, vertigo, double vision and large dark spots before the eyes?

A. J. SIMPSON, M.D., Kenilworth, N.J.

ANSWER—Faced with manifestations so serious as severe hematemesis the situation would seem to demand the elimination of the offending agents since others less harmful undoubtedly may be substituted.

The percentages of the constituents mentioned in the query are not specified but it is assumed that wood alcohol and benzene make up the bulk of the cleaning agent. Wood alcohol definitely is undesirable for this operation if the inhalation of appreciable quantities of vapors takes place.

Many of the manifestations mentioned may be produced by either wood alcohol or benzene or by a combination of the two. It is noted in the query that some other petroleum products might be present. The hematemesis and the diarrhea suggest the presence of some chlorinated hydrocarbon, such as carbon tetrachloride.

By way of remedy, the wood alcohol should be eliminated from the formula. If practical, higher boiling point petroleum derivatives, such as Stoddard's solvent, should be substituted for the benzene, in order to lessen the evaporation.

Work in booths, or at least under conditions providing for the entrainment of vapors, is desirable. Positive pressure masks are efficacious but are cumbersome and uncomfortable for the workers.

If chlorinated hydrocarbons should prove to be present, a high calcium diet with abstinence from alcohol is desirable.

A small amount of this shoe cleaning agent probably enters the worker's body by way of the skin. The method of application to the shoes should be such as to break contact between the cleaning fluid and the skin.

The testing of the urine of sick workers for wood alcohol or for formaldehyde is likely to yield proof of the part played by this constituent in the causation of the abnormality. This urine may be tested in the following manner:

Distill a small portion of the urine over a steam bath. To 5 cc. of the distillate that may or may not contain methyl alcohol add 2 cc. of potassium permanganate acid solution made up in the manner later described. Allow this to stand ten minutes. Add 2 cc. of oxalic acid prepared as described. When all color has disappeared add 5 cc. of modified Schiff's reagent.

The characteristic blue or pinkish color may appear within a few seconds and at least within ten minutes. Delicacy, 1 in 7,000.

To make the permanganate acid solution add 3 Gm. of potassium permanganate to 15 cc. of 85 per cent phosphoric acid and dilute to 100 cc.

To make the oxalic acid solution add 5 Gm. of oxalic acid to 100 cc. of 1:1 sulphuric acid.

To make the modified Schiff's reagent add 0.2 Gm. of rosaniline hydrochloride to 120 cc. of hot water. Cool and add 2 Gm. of anhydrous sodium sulphate dissolved in 20 cc. of water. Add 2 cc. of concentrated hydrochloric acid. Dilute to 200 cc. and keep in a glass stoppered amber bottle.

DYSMENORRHEA

To the Editor—Mrs. O. aged 36 who weighs 152 pounds (69 kg.) and whose height is 5 feet 6 inches (167.6 cm.) has had painful menstruation since she was 12 years of age. The menstrual periods occurred at twenty-eight day intervals and lasted seven days. A cystic ovary was removed in 1919. A baby was born in 1928. Extensive perineal lacerations occurring at this time were not repaired. Examination reveals no other abnormality. Three weeks following confinement she commenced having severe cramps for which she was treated with radium. Since the radium was used there has been no flow but there occurs each month most excruciating pain. This paroxysm is followed by a second one in one week which in turn is followed in one week by a severe occipital headache radiating downward along the spine. High voltage roentgen treatments in 1931 gave no relief. Ovarian extract has been ineffectual. Please omit name. MD Nebraska

ANSWER—The pain may be due to cervical stricture incident to use of the radium to radiation changes in the ovary, or to neurosis incident to the induced menopause. Pelvic adhesions or exudates sometimes complicate radiation therapy and may be a factor here.

In treatment the cervix should be dilated to make certain that there is no stricture. Ovarian therapy will be of little avail, with the possible exception of theelin or lutein. Other treatment should be along the lines followed in the usual care of a nervous woman in the menopause. Sedatives, life outdoors and small doses of thyroid are of most aid.

THE PERIOD OF CONCEPTION

To the Editor—There are two articles on the term of conception in women and the menstrual cycle abstracted in *THE JOURNAL* June 18, 1932 and Aug. 12, 1933 from the *Zentralblatt für Gynäkologie* of March 19, 1932 and June 17, 1933. The abstracts are incomprehensible and lead one into a maze of confusion owing to the fact that periods of days are stated in numbers from the beginning or end of the menstrual cycle without stating whether inclusive of the numbers mentioned or not. A perusal of the articles will I am sure make clear and I shall appreciate having an interpretation of each of the articles that will leave no doubt as to their meaning particularly as pertains to their expression of the number of days in certain fractions of the menstrual cycle. Please omit name. MD Illinois

ANSWER—Neither Ogino nor Knaus mentions the word "inclusive" when giving the number of days in question. Our abstracts do not interpret articles but are limited to reporting faithfully whatever statements are made by the authors.

Ogino whose report is abstracted in *THE JOURNAL* June 18, 1932 gives a precise formula. In the cycle of twenty-eight

days he states that the period of conception is between the tenth and seventeenth days. In a woman whose cycle fluctuates between twenty-six and thirty-two days, the beginning of the period of fertility would be $10 + (26 - 28) = 8$ days after the onset of the flow, and the end would be $17 + (32 - 28) = 9$ days. Consequently, conception would take place in the time between the eighth and twenty-first days after the onset of menstruation.

In the abstract published in *THE JOURNAL*, Aug. 12, 1933 the statement is made that Knaus contends that, in women with a regular menstrual cycle of twenty-eight days, conception can take place from the eleventh to the seventeenth day of the menstrual cycle, and that the day of ovulation is determined by subtracting fourteen days from the length of the cycle. He illustrates this in the following manner: In a regular cycle of twenty-six days, for instance, ovulation takes place on the $(26 - 14)$ twelfth day after the onset of menstruation, in a regular cycle of twenty-eight days on the fourteenth day, and in a cycle of thirty days on the sixteenth day. However if the length of the menstrual cycle fluctuates in the course of a year, that period which begins with the ovulation day of the shortest cycle and ends with the ovulation day of the longest cycle would be considered the term of ovulation. Thus, in a woman whose cycles fluctuate between twenty-eight and thirty-two days ovulation may take place between the fourteenth and eighteenth days after the onset of the last menstruation. Taking into consideration the short life of the two gametes, conception would in this case be possible only in the time from the eleventh to the nineteenth day of the cycle.

CAUSE OF PLEURITIC PAIN DURING MENSTRUATION

To the Editor—A woman aged 20 married five months complains of pleuritic pain at the base of the left lung present only during the menstrual periods (lasting about five days) and about the time of ovulation (lasting one day). This pain has been present periodically ever since an attack of pleurisy three years ago and is getting progressively worse confining the patient to bed during the attacks. Between the attacks the patient is up and around feeling fine. Careful physical examination made between the attacks does not reveal anything abnormal. Laboratory examination (urine and blood) is negative. The patient has consulted many physicians without any benefit. Is this a case of endometrial tissue being present at the base of the left lung or what is it? Have you any suggestions as to diagnosis and treatment?

JAMES L. MILOS, M.D. Chicago

ANSWER—No endocrine process is known that would explain such attacks of pain on an organic basis. It may be that adhesions at the base of the left lung are present and are producing some discomfort and that during the menstrual periods the patient's sensitivity to pain is greatly increased. On the other hand, it is equally possible that a psychic conflict is associated with these sexual processes and that the chest pain is a neurotic expression of this.

The question regarding endometrial tissue being present at the base of the left lung and producing periodic pain at the menstrual periods is difficult to answer. If such is the case it must be a rare, in fact, unique observation. No suggestions as to treatment predicated on the facts that are presented are offered.

HABITUAL ABORTION

To the Editor—I have a 30 year old patient now pregnant who has had six previous pregnancies and six spontaneous evacuations of the uterus. Two of these occurred at six weeks one at two months one at three months and two at six months. In all of these the evacuation process was easily accomplished with no great amount of pain and was in the process of completion before the patient had any warning that such a thing was going to happen. In every case as in the present pregnancy she was anxious to avoid such an occurrence as she is desirous of having children. I have eliminated syphilis as a cause. I believe. At least numerous Wassermann tests have all been negative and she has never had any clinical signs of syphilis. Normally the uterus is not large and I cannot outline or find any trace of any growth in the uterine wall that might be causing this. I am now seeking information as to what could be the cause in order, if possible to save the present pregnancy from the same fate. Can you advise me directly, or by reference along the line of information I am seeking? MD Kansas

ANSWER—Cases of habitual abortion are the most unwell come to all obstetricians because so little is known about them. Syphilis rarely causes early abortions and is easily ruled out. Naturally a careful general physical examination is to be made to find any constitutional disease, nephritis, hemopathia, diabetes or focal infection.

In the case cited—congenitally underdeveloped uterus may be the reason and little can be done—and that little lies in the newer endocrines, anterior pituitary and corpus luteum hypodermically and by mouth, both however, in the experimental stage. Corpus luteum has some sponsors. Complete

rest in bed (with the foot end raised 8 inches) throughout the length of pregnancy should be insisted on. So many remedies have been suggested that one is ashamed to list them. If the basal metabolism reading is low, thyroid is indicated and in all cases roborant tonics are given with an abundance of all the vitamin-bearing foods. Iron and calcium, arsenic, mercury and iodine, the two first in fair size doses, the other three in small dosage are routine. Although rarely concerned, the husband may not be able to transmit a strong enough life impulse to an ovum to carry it through nine months. De Lee's Obstetrics, 1933, has a short but informative chapter on the subject.

RELATIONSHIP IN USE OF VIOSTEROL AND INSULIN

To the Editor—*I have under my care a young lady who is diabetic and seven months pregnant. By the use of insulin and a carefully arranged diet she has been kept sugar free to date. A few weeks ago she complained of pains in her arms and limbs which suggested the usual 'neuritis of pregnancy.' Following the experience of others I placed her on 7 minims (0.4 cc) of viosterol three times a day. She immediately showed an increase of sugar on the same dosage of insulin and diet. A 35 per cent increase in insulin was required to clear the urine. A few days later the viosterol was stopped and it was possible to reduce the insulin dosage. As soon as the viosterol was resumed sugar returned. It has not been practical to determine the blood sugar in this case. What is your explanation for this condition?*

C B JOHNSON MD Eudora Kan

ANSWER—The data furnished do not warrant conclusions. Were the values for carbohydrate, protein and fat for the two periods without viosterol and the two periods with viosterol precisely the same? Did the patient always eat the food served? Were the quantities of sugar and the percentages of sugar in the urine so consistent as to indicate that all the urine was collected daily? Blood sugar tests are almost essential in the critical analysis of a patient with diabetes and it would have been instructive to compare the values obtained with those for blood calcium. Was insulin always given at the same time? Diabetes is treated with diet exercise and insulin. Was the amount of exercise similar in the two periods?

GRATING SOUNDS IN JOINTS

To the Editor—Several days ago a woman aged 37 consulted me for a complaint of squeaking joints beginning in the left knee ankles shoulders wrists and neck. There is no pain attached only an annoyance because of the sound which can be heard several feet distant. She has never had an inflammation of joints. The past history reveals chronic sinusitis for nine years with several operations including submaxillary resection. Also mastoiditis at the onset with operation and tonsillectomy at the onset. There has been no trouble with the sinuses since she moved from the seaside four years ago. Suspension of the uterus with right tubo-ophorectomy was done eight years ago and cervical cautery treatment at that time suggests gonorrhea but the patient says that smears at that time were negative. The patient has been divorced seven years. She has two children 16 and 12 years of age. The menses are normal. She feels fine except for the joints. Physical examination is negative except for the joints. No deformity is apparent. Motion of the joints causes a creaking sound with a palpable vibration. It is most marked in the knee. It seems subpatellar. Roentgen examination of the left knee two years ago was reported negative. The patient asks whether the condition may cause a disability in the future. This seems to me to be an early osteoarthritis (degenerative arthritis deformans) and I should appreciate any suggestions for procedure and treatment. Please omit name.

MD, California

ANSWER—"Soft grating" due to hypertrophied fringes and patellar fat pad is common especially in women more particularly in obese women in or past middle age. In the majority of cases this is merely a special localization of general hypertrophy of adipose tissue and the hypertrophied fat fringes are of significance merely in the light of their mechanical interference with the function of the knee.

Hard grating may indicate synovial hypertrophy with definite histologic changes in the synovia thickening induration often cartilaginous metaplasia in the hypertrophic synovial villi and multiple free bodies as in osteochondromatosis of the knee.

For simple fatty hypertrophy of synovial villi and fat pads of the knee without osteoarthritic changes it is sufficient to elevate the heels (relaxation of the gastrocnemius) to wear an elastic knee cap and to strengthen the extensor apparatus of the knee which has become relaxed by irritative effusions and villous stasis in the knee by systematically massaging the quadriceps muscles. Such patients should refrain from kneeling heavy lifting prolonged standing and violent exercises of their knees although they should be permitted and encouraged to take mild exercises necessary for their general health. Troublesome hypertrophied pads may be removed through a short median incision and in the absence of any degenerative changes of the knee (osteoarthritis) give a good prognosis.

PORT WINE MARKS AND NEVI IN CHILDHOOD

To the Editor—My baby is 3 weeks old and was born with several port wine marks on its face which are probably telangiectatic spots of the simple flat type. There is one about 25 mm across on the back of the neck which is somewhat covered by the hair of the head. On the face there are several segregated spots situated on the right lid the nasion the left eyebrow and the tip of the nose. These facial spots are rather pinkish and are about one-eighth inch in diameter. I was told that they will probably disappear spontaneously in several months. However I should like to know whether they do disappear spontaneously and what remedies might be employed for removal also what results might be expected.

MEYER E AISBEL MD Brooklyn

ANSWER—The lesion on the back of the neck may be a port wine mark. Unfortunately, there is no satisfactory treatment for port wine marks. In the opinion of most dermatologists radium and x-rays are contraindicated. The lesion can probably be destroyed with blistering doses of ultraviolet radiation or with solid carbon dioxide. However a great many treatments are often necessary over a period of a year or two. In view of the difficulty of eradicating port wine marks, and in view of the fact that it is on the back of the neck and will be covered by hair when the child is older, it is advised that it be let alone.

The description of the lesions on the face suggest what are called spider nevi rather than port wine marks. Port wine marks never disappear spontaneously. Spider nevi often do disappear spontaneously. It is suggested that no treatment be given at present. If they do not disappear they usually can be completely eradicated without scars by the method of electrolysis, provided the electrolysis is expertly applied. It is customary to wait until the child is 2 or 3 years of age or even older before applying the treatment.

TREATMENT OF SYPHILIS

To the Editor—A man aged 28 who is under my care has syphilis. His initial lesion was misdiagnosed by a physician and when he first came to me over a year ago he had had secondaries for several weeks. The Wassermann reaction is 4+. I treated him with ten injections of neoarsphenamine 0.9 Gm at weekly intervals. The Wassermann reaction was 3+. After ten injections of iodobismutol into the buttocks at weekly intervals the Wassermann reaction was negative. A rest period of three weeks was given followed by ten more injections of neoarsphenamine 0.9 Gm. The Wassermann reaction continued negative. Ten injections of thiothymol were given. The Wassermann reaction was negative. The Wassermann test was repeated again in about a month and found to be negative. About three months later the patient returned suffering from headaches and scattered discrete brown macules about the body. The Wassermann reaction was four plus. I immediately started a series of neoarsphenamine injections. I should like to know how I should proceed with this case which I thought I had cured. How long and what treatment should he given? At present after having had about six injections of neoarsphenamine the patient is complaining of loss of pep aching muscles dull aching in the head as if the brain were too big for the head and vertigo when the head is bent back. He states that after exercise when he sweats considerably he feels fine but that at all other times he notices the symptoms mentioned. Is this due to the accumulation of arsenic in the body? That is my opinion as I could find no other condition present to which the symptoms might be attributed. Should I change my treatment because of these symptoms? Please omit name and address.

MD, Illinois

ANSWER—The amount of treatment that is thought necessary by leading clinicians to cure early syphilis shows wide variations. This patient has developed a relapsing secondary syphilid after an apparent cure. There are not enough data available to suggest the possibility of this being a reinfection. Treatment should be continued with a course of neoarsphenamine and bismuth compounds in more moderate dosage. Few syphilologists advocate as high a dosage as 0.9 Gm of neoarsphenamine. The symptoms complained of might indicate impending arsenical encephalitis. Another possibility is early syphilitic meningitis. A spinal puncture should be done at this stage and the appropriate treatment will depend in part on the outcome of the test.

MORPHINE AND DIGITALIS IN ANGINA PECTORIS

To the Editor—I recently read that Attlinger believes that morphine is contraindicated in angina pectoris. I have used it for years when life seemed saved by it. Do you think one is justified in its use in severe attacks? Is the use of powdered leaves of digitalis any more likely to have a laxative effect than the use of potent tincture of the tincture?

NATHANIEL F CULVER MD Greenfield Vt

ANSWER—The article referred to by Attlinger is not convincing especially as it is recommending a proprietary drug in place of morphine. It is based partly on clinical experience and partly on the physiologic effects of morphine in experimental animals. Morphine in some experimental animals has a much stronger effect on the vagus than in man and one does not see the same effect on heart rate and conductivity in man.

that is seen in experimental animals. The experience of most clinicians would favor its use in angina and in coronary thrombosis and would not support the view that it resulted in any coronary vasoconstriction or in producing any abnormal rhythm. Roger Froment, in a recent monograph, also states that it may be contraindicated but does not give any cogent reasons. It probably should not be used to the point at which it has a depressant effect on respiration.

The use of powdered digitalis leaves should not have any more laxative effect than a corresponding dose of the tincture.

HEMATURIA AFTER METHENAMINE

To the Editor—If so much methenamine is given in excessive doses over a long period of time that it causes hematuria, what is the source of the blood cells in the urine?

FRED S. WATSON, M.D., Okmulgee, Okla.

ANSWER—When excessive doses of methenamine are given over a long period of time and hematuria occurs, the general consensus seems to be that the bleeding is vesical in origin.

Cystoscopic examination in some of these cases has shown the presence of a hemorrhagic cystitis.

Postmortem examinations in some fatal cases have shown that the bleeding came from the mucous membrane of the bladder. It is generally believed that because of the rapid elimination of the methenamine the kidneys do not suffer irritation and do not bleed. In some of the autopsy cases hyperemia of the kidney pelvis was found.

CHEMICAL TESTS FOR INSULIN

To the Editor—Has a chemical test for insulin in body fluids or tissues been devised? If so, is it reliable? Please describe.

F. E. CLOW, M.D., Wolfchboro, N. H.

ANSWER—No chemical test specific for insulin has yet been devised. When it is known to be present in a solution containing little else, its quantity may be estimated by observing its hypoglycemic action when injected into animals (usually rabbits or rats). The determination of the presence or amount of insulin in body fluids or tissues is complicated by the presence of other substances that may exert hyperglycemic or hypoglycemic actions. Such determinations have therefore usually been made only after a preliminary extraction of the insulin in a manner similar to that in which it is obtained from pancreas. The subject of insulin in tissues other than the pancreas was discussed by C. H. Best, C. M. Jephcott, and D. A. Scott in the *American Journal of Physiology* 100:285 (April) 1932.

OXYGEN PERCENTAGE AT VARIOUS ALTITUDES

To the Editor—What percentage of oxygen should I expect to find at an altitude of 600 feet as at Charleston, W. Va.? I see in an editorial in the July 22 issue of *THE JOURNAL* that at an altitude of 8,000 feet the oxygen content is 15.35 per cent, and at an altitude of 20,000 feet 9.4 per cent. The question is: Can this oxygen content be depended on in practically all sections of the country or is there a marked variation to be found in different localities? The barometric pressure here averages 29.65 or about 750 mm. with slight variations.

WIRT B. WILSON, M.D., Charleston, W. Va.

ANSWER—The partial pressure of oxygen at an altitude of 600 feet above sea level is not sufficiently lowered to present any physiologic problem in respiration. At a given altitude the relative proportion of oxygen is essentially the same everywhere under comparable conditions. Small variations in the content of carbon dioxide and that of gases included through industrial or other conditions do not affect in any significant way the partial pressure of oxygen, though such constituents as carbon monoxide may become objectionable in rare instances.

ABNORMAL MENSTRUATION

To the Editor—A girl, well developed and proportioned, aged 11 years and 8 months, 4 feet 11 1/4 inches (151 cm.) tall, weighing 120 pounds (54 Kg.) has started menstruating for a period of seven or eight days and profusely. Her mother and grandmother have this history before her. Her basal metabolism rate is -6; otherwise she appears normal. Any suggestion as to the future conduct of this case will be greatly appreciated. Please omit name and address.

M.D., Texas

ANSWER—Presuming that a local examination has revealed no apparent cause for the bleeding from the uterus and vagina such as a malignant condition or polyps, one might think of an abnormal endocrine function and the latest theories point to the anterior lobe of the pituitary body, which seems to be the general regulator of the ovary and uterus.

From the mass of contradictory reports regarding the effects of theelin, progesterin, progynon, and so on, it is difficult to select

a remedy. Success, however, has been obtained in a few cases by administering the blood of the mother subcutaneously in 20 cc. doses. Experimentally, one might try the blood of the mother taken at the time of her menstruation or the blood of a pregnant woman. Recently, in one similar case, the latter seemed to have a good effect. A small dose of thyroid should be given.

Failing endocrinal treatment, a curettage is the next procedure.

USE OF OIL IN MASSAGE

To the Editor—Please give me formula for a good oil to be used in massage for arthritis. Kindly omit name.

M.D., Illinois.

ANSWER—The routine use of oil as a "lubricant" in massage is, in general, to be deprecated. Talcum powder is more useful than a fat, in many cases. When a fatty lubricant is needed, as on a sensitive and dry skin, the sparing use of white petrolatum is all that is required or desirable. If in a case of arthritis, rubefaction is wanted along with massage, a liniment may be employed during the manipulations, and, assuming the arthritis to be possibly of rheumatic origin, methyl salicylate (20 per cent) added to liquid petrolatum might be the best.

CRIBBING IN HORSES

To the Editor—What is the human counterpart, if any, of the disease in horses known as "cribbing"? What are the symptoms and what is the name of the disease? No references on the subject are available here. Please omit name.

M.D., Wisconsin.

ANSWER—There is apparently no disease in human beings which is the exact counterpart of cribbing in horses. In cribbing the animal grasps the manger or some other object with the incisor teeth, arches the neck, makes peculiar movements with the head and swallows quantities of air. The nearest resemblance to this condition is aerophagy, in which human beings swallow considerable quantities of air, which is there after eructated, and pica, a craving for unnatural articles of food or a depraved appetite seen sometimes in children, in cases of hysteria, in chlorosis and in pregnancy.

IDIOPATHIC MUSCULAR ATROPHY

To the Editor—I have under my care a white man in his early thirties who is suffering from progressive muscular atrophy. He noticed the first symptoms at the age of 15 years. The progress of the disease has been rather slow but nevertheless steady. The muscular flaccidity and wasting at present are manifest almost entirely in the lower extremities and the muscles of the thumb. The blood and spinal fluid Wassermann reactions are negative and he has a normal colloid gold curve. Kindly give me information as to any treatment that will arrest the progress of the disease or that will cure him. Kindly omit name.

M.D., South Carolina.

ANSWER—This presumably is a case of idiopathic muscular atrophy, also called muscular dystrophy and not spinal muscular atrophy. The most recent and most promising treatment for dystrophy is the giving by mouth twice a day of about half an ounce of glycine (glycocol). Another treatment advocated on theoretical grounds and which seems to have given some results is hypodermic injection of epinephrine and pilocarpine.

SNEEZING AS A SYMPTOM OF COLD ALLERGY

To the Editor—In *THE JOURNAL*, September 16, Dr. S. M. Feinberg explains the sneezing of the vasomotor rhinitis patient on arising in a comprehensive manner. In observing a number of patients similarly afflicted, I have found most of them to be also definitely allergic.

I should like to emphasize the probability of an allergy to cold. While the victim is in bed his skin temperature more nearly approaches that of the body than at any other time. The mere act of throwing off the bed clothes and either touching the floor or getting into slippers abruptly lowers the skin temperature. Thus the congestion of the sphenoidal area and the entire perinasal mucosa appears with resulting sneezing.

This line of reasoning is brought to mind by the dramatic motion pictures which Duke displayed at the Milwaukee session of the American Medical Association. He showed acute attacks of asthma precipitated by heat or cold in victims susceptible to either.

Following his therapeutic suggestions, the treatment for the sneezing patient would be gradual desensitization by increasing the skin tolerance to cold with graduated colder shower baths ending up in time with possibly rapid friction of the skin with ice. This is of course with the premise that the patient is allergic to cold.

Many examples exist of such patients who sneeze when a window is opened in a warm room or who sneeze on going outside into cold air and yet do not develop any subsequent respiratory infection. In one case in particular, sneezing and nasal congestion could be produced by running hot water on the wrist and hand and placing the wet parts in the crack of a partially opened door during cold weather. This illustrates the minute sensitivity of such patients.

RONALD B. ROGERS, M.D., Neenah, Wis.

Book Notices

Medical Relations Under Workmen's Compensation A Report Prepared by the Bureau of Medical Economics American Medical Association Paper Price 75 cents Pp 167 Chicago American Medical Association 1933

Workmen's compensation laws regulations and court decisions have been the subject of many articles and reports This report of the Bureau of Medical Economics is the first study of workmen's compensation in the United States in which an attempt has been made to trace from the beginning of workmen's compensation laws the relation of the medical to other phases of compensation administration

The evolution of the present system of compensation is traced in chapter I Chapter II is devoted to a discussion of the prevention of accidents Attention is drawn to a shifting attitude toward accident prevention from great emphasis, in former years on the care and maintenance of equipment to the present growing attention to the human element in industry

One chapter is devoted to a description of the evolution of administration of workmen's compensation In this discussion particular attention is given the insurance carriers It is pointed out that

methods of administration like the original legislation depend far more on the continuous intelligent application of pressure by the interests involved than on differences in laws and administrative forms Employers and insurance companies have been continuously alive to their interests and skilful in pressing them The physicians have shown less capacity to protect their interests and have suffered the consequences of that incapacity

In closing the discussion on the growth in the provisions for medical care the opinion is advanced that

Without in any way disparaging the function of other factors in the field of compensation it seems to be a very conservative conclusion that the neglect of the medical factor in the early stages has handicapped all the workings of compensation and that one of the most pronounced features of the evolution of compensation has been the increased recognition of the importance of the medical factor at every stage

Subjects that should be of special interest to all physicians who are in any way affected by workmen's compensation are

"Choice of Physicians," "Payment for Medical Service" and "Professional Relations in Compensation"

It is somewhat difficult to assign the responsibility for the completely successful although usually silent opposition to every effort to secure medical representation or adequate pay for the physicians employed in compensation administration The employers and insurance carriers can probably be assumed to belong to this opposition as a part of their effort to keep down payments to physicians Members of commissions naturally react against any move that would reduce their authority So it remains true that the physicians who are the only persons concerned with compensation who have undergone a long course of training to prepare them for their work and whose decisions are so vital to every action still remain the lowest paid and with almost the least influence in compensation administration of any parties concerned

Among the conclusions it is suggested that there should be free choice of physicians, within certain limitations there should be no solicitation or compulsion exercised on patients, all expenditures for medical care should go to those who give that care, and there should be medical representation in all compensation institutions proportionate to the medical interests involved

This report should be valuable to all county and state medical societies, industrial commissions or departments and insurance carriers handling workmen's compensation cases The work is made more valuable by a number of charts, graphs and tables

Die Lungentuberkulose Von Dr med H Gissel Facharzt für Chirurgie und Dr med P G Schmidt Facharzt für Lungenkrankheiten Mit einem Geleitwort von Prof Dr W v Gaza Paper Price 18 marks Pp 201 with 121 illustrations Leipzig Georg Thieme 1933

Gaza states in the introduction of this monograph on pulmonary tuberculosis by his pupils Gissel and Schmidt that it is needed because of the team work of physicians and surgeons brought about by recent advances The newer pathologic conceptions regarding the development and hematogenous spread of pulmonary tuberculosis and the increased knowledge regarding the culture and the morphology of the tubercle bacillus, are also matters which Gaza feels warrant this publication. As would be expected under such guidance the work starts with a brief but scholarly review of the general history of tuberculosis The authors conclude this chapter with a review of the factors responsible for the declining death rate attributing this to better living standards, economic conditions, earlier diagnosis and improved therapy The possibility of the decline being due to epidemiologic laws is not discussed England and Germany are given the lowest death rates for 1928, namely, 90 per hundred thousand living The tubercle bacillus is thoroughly dealt with in regard to varying morphology the possibility of filtrable types and the modern cultural and staining procedures The virulent smooth form of culture and the avirulent rough form are discussed in regard to Calmette's BCG Allergy and immunity are discussed and also the matter of droplet and dust infection While the latter is perhaps of greater importance, it is pointed out that the larger droplets expelled when a patient coughs may contain upward of 23,000 tubercle bacilli

Excellent colored plates depict phases of the pathology of tubercle in the lungs The conception of Liebermeister and Lowenstein of the frequent escape of tubercle bacilli from the hilus glands into the blood stream is accepted with its significance in the spread of the disease History taking in diagnosis is rightly stressed Only praise can be given the chapters on the symptomatology physical examinations, course of the disease laboratory tests and roentgen examinations The reproductions of the roentgenograms of the chest are exceptionally good Every phase of the disease is depicted from a large number of films Tuberculous pleurisy is pictured and described Bed rest is advised only until the disappearance of the friction rub or the complete absorption of the exudate This is not sufficient One cannot agree that artificial pneumothorax of a healthy lung should be undertaken to promote the delayed absorption of fluid on the opposite side nor can one entirely agree that the reason for the serious relapse with pulmonary tuberculosis in upward of 30 per cent of patients with uncomplicated pleurisy often within a year is due to the pleurisy having been of hematogenous spread It is more probable that the reason for so many patients with a history of pleurisy with effusion suffering relapse with serious lung involvement is that as a result of the fluid compression, extensive paren

chymatous lesions may have temporarily disappeared. The roentgenograms after the fluid has disappeared are therefore apt to be misleading. A few extrapulmonary forms of tuberculosis are described especially the commoner complications. In the treatment of laryngeal disease rest by silence, should be placed first rather than last. The sanatorium cure and the climate of altitude are recommended. It would seem that complete rest in bed over a prolonged period after fever has disappeared and symptoms have improved is not sufficiently stressed.

The surgical methods of treating pulmonary tuberculosis are well illustrated and discussed and the history of each procedure is related. The differential diagnosis treats of the numerous forms of bronchial and lung disease that may be mistaken for tuberculosis. The recognition of tuberculosis as a *volks-seuche* is not neglected and the social steps to combat the disease are outlined. The book should be a valuable addition to any tuberculosis library.

Nutrition. By Graham Lusk, ScD, MD, LL.D., N. Clin. Medica. A Series of Primers on the History of Medicine. Edited by E. B. Krumbhaar, MD. Cloth. Price \$1.50. Pp. 142 with 13 illustrations. New York: Paul B. Hoeber, Inc. 1933.

Here is another primer in the series of medical historical items now being published by the Hoeber press. This volume was finished just before the death of Dr. Lusk on July 18, 1932. Nutrition is of course, as old as man. Tracing its history, Dr. Lusk shows its outgrowth from general medical knowledge and the developments of physiology and chemistry to its development as a specialty of medical science beginning with the last two centuries. After discussing these original developments, Dr. Lusk traces chronologically the advances of the nineteenth century in various nations. In a final chapter on the modern phase he calls attention particularly to the development of calorimetry. He concludes with the statement: 'Even in medical schools little thought is given to this subject. The schools of home economics however, form a group of people who really understand the subject.' This indictment of medicine is probably warranted in large part and certainly constitutes a challenge to the medical profession.

The Treatment of Rheumatoid Arthritis and Scleritis. By A. H. Douthwaite, MD, FRCP, Assistant Physician, Guy's Hospital, London. Second edition. Cloth. Price 6/- Pp. 131 with 4 illustrations. London: H. K. Lewis & Company, Ltd. 1933.

In this edition the work has been revised to embrace an epitome of the results of modern research in the treatment of rheumatoid arthritis. A chapter on the diagnosis and treatment of sciatica is included. The book is divided into two parts containing four chapters each. The first part deals with the etiology of rheumatoid arthritis and the first chapter is devoted to the classification of arthritis and to distinguishing each of the following from the others: rheumatoid or atrophic arthritis, menopausal rheumatoid arthritis, osteoarthritis or hypertrophic arthritis, and infectious or pseudo-atrophic arthritis. Rheumatoid or atrophic arthritis is defined as a disease affecting almost exclusively women of child-bearing age and characterized by well marked constitutional changes accompanied sooner or later by symmetrical swelling of many small joints brought about by periarticular changes. In chapter II is considered the part played by focal infection in the etiology of this type of arthritis and its importance is rather minimized. Rheumatoid diathesis is reviewed in chapter III and the question of vitamin deficiency is discussed. Chapter IV includes discussions concerning metabolic changes and observations on biochemistry. In the second part of the book the various types of treatment are summarized. In the first chapter is outlined the treatment of early rheumatoid arthritis, and discussions concerning diet, heat, elimination of foci, vaccine and medicinal treatment and massage are included. The second stage of the disease is discussed in the next chapter and the uses of splints, passive motion and radiant heat are discussed. The treatment for deformity or the third stage is next considered and medicinal non-peptic protein therapy as well as manipulation and splints is considered from the standpoint of relative merit. The final chapter is devoted to a discussion of sciatica: its diagnosis and treatment. According to the author the term 'sciatica' refers to a symptom and not a clinical entity and consists of pain felt in the course of the sciatic nerve. The classification of primary, secondary, central and peripheral

types of sciatic neuritis are discussed with regard to their etiology. This chapter is satisfactory except that mention is not made of tumors of the spinal cord and of congenital developmental narrowing of the intervertebral foramina of the lower lumbar vertebrae. The treatment of sciatica as laid down is not discriminative and therefore is misleading in places. Nerve stretching, acupuncture, and injection directly into the nerve are discussed as though there were no associated dangers of disability following such treatment. The book is interesting and should prove of value to those who do not wish an exhaustive study of the subject but merely a cursory summation of facts brought down to the present.

The Heroic Age of Science. The Conception Ideals and Methods of Science Among the Ancient Greeks. By William Arthur Heldel, Research Associate of the American Council of Learned Societies of the Carnegie Institution. Published for the Carnegie Institution of Washington. [Publication No. 442.] Cloth. Price \$2.50. Pp. 203. Baltimore: Williams & Wilkins Company. 1933.

The early Greeks laid the foundations of science. The author gives a nice evaluation of the Hippocratic contributions and of the work of Aristotle, and of the writings of Theophrastus and other important Greek contributors. The Greek method was essentially accurate observation and careful recording of results. It involved the framing of generalizations and then the testing of those generalizations by fact. In his essays the author discusses observation and induction as used by the Greeks, then classification, analogy and experimentation. This, obviously, is the procedure for all scientific work. Greek science was characterized by a free play of intellect. Even though many of the discoveries announced as those of Greece had been brought in from other countries the Greek method carried this knowledge to a height of perfection not reached elsewhere.

Holt's Diseases of Infancy and Childhood. A Textbook for the Use of Students and Practitioners. By the late I. Emmett Holt, MD, and John Howland, MD. Revised by L. Emmett Holt, Jr., MD, Associate Professor of Pediatrics, Johns Hopkins University, and Rustin McIntosh, MD, Carpenter Professor of Diseases of Children, Columbia University. Tenth edition. Cloth. Price \$10. Pp. 1240 with 209 illustrations. New York & London: D. Appleton & Company. 1933.

In this the tenth edition of the original book by L. Emmett Holt, Sr., extensive changes have been made. The sections on nutrition and nutritional disorders, the deficiency diseases and diseases of the blood and diseases of allergy have been completely rewritten and have also many other sections. New articles have been added on chemical relations in childhood, immunology, serum diseases, burns, lead poisoning, dwarfism, encephalitis and many of the infectious diseases. Several contributors in addition to the two authors responsible for the text have contributed the sections on various subjects so that the work more nearly approaches a system of pediatrics than a volume representing the views of one authority. The first edition of this work as explained by Dr. E. A. Park was an event in the history of pediatrics in this country for it codified and defined this subject and separated it clearly from general medicine. The death of Dr. Howland who succeeded Dr. Holt in the production of this work caused it to devolve on the present editors. They have had an excellent foundation on which to build so that the text now available may be considered authoritative, modern and perhaps the most useful of all the general textbooks available in this field.

Internal Medicine. Its Theory and Practice. In Contributions by American Authors. Edited by John H. Muer, BS, MD, F.A.C.P., Professor of Medicine in the Tulane University of Louisiana School of Medicine. Cloth. Price \$10. Pp. 1316 with 39 illustrations. Philadelphia: Lea & Febiger. 1932.

This volume has now been before the medical profession for almost a year and has had wide acceptance as a useful text book as well as a reference work for the office and the hospital. The contributors have been chosen as recognized authorities on the problems they discuss and have been given considerable latitude in the development of their chapter. Repetition has been avoided by grouping the diseases according to certain classifications, discussing first the characteristics common to the group and secondly the special problems associated with individual diseases. Moreover there is an excellent suggestive bibliography following the discussion of each disease. The volume proceeds in four parts to discuss the infectious disease, systemic disorder, disease of internal organs, and the

lism, physical and chemical agents, and finally diseases of the nervous system. Because of its authenticity the book may be especially recommended as a modern textbook of the practice of medicine.

The Anatomy of the Eye and Orbit Including the Central Connections, Development and Comparative Anatomy of the Visual Apparatus. By Eugene Wolff, Ophthalmic Surgeon, Royal Northern Hospital, London. Cloth. Price 31s. 6d. Pp. 310 with 173 illustrations. London: H. K. Lewis & Company, 1933.

This is a concise, profusely illustrated book on the anatomy and anatomic neurology of the eye and orbit. It is so written as to give the essential structures and their relations and interrelations to the cranial anatomy, especially the neurologic anatomy, without tiring the reader with the unessential or the minute details that would be of interest chiefly to the research worker. The material is arranged in a logical order, the bony orbit and accessory sinuses being given in chapter I. Chapter II deals with the sclera, choroid and retina. In chapter III the lids, muscles, conjunctiva and lacrimal apparatus are described. The gross description and histomicroscopy of the anterior segment of the globe as well as the vitreous is treated in chapter IV. Chapter V describes the external ocular muscles and Tenon's capsule. The cranial nerves associated with the eye as well as the ciliary ganglion are discussed in the first part of chapter VI. The optic nerve and its central connections, the involuntary nervous system and pathway of the light reflex complete this chapter. Chapter VII deals entirely with the embryology and postnatal growth of the eye, and the last chapter contains in its fifty pages a good outlined summary of our knowledge of comparative anatomy. Under the title of practical considerations, the author in several chapters introduces the clinical significance of lesions or disease of various structures. The illustrations, many of which are original, are well selected and though they are all black and white they serve materially to illustrate and clarify the text. The book presents little clinical ophthalmology but does give the anatomic basis for clinical study.

The Control of Football Injuries. By Marvin Allen Stevens, M.D., Assistant in Surgery, New Haven Hospital and Winthrop Morgan Phelps, M.D., Professor of Orthopaedic Surgery, Yale University. Cloth. Price \$3. Pp. 241 with illustrations. New York: A. S. Barnes & Company, 1933.

The authors of this volume include a physician who was also head football coach of Yale University, and the professor of orthopaedic surgery in the same university. Being themselves responsible for the care of the athletes in that school during the football season they write with authority and experience. They have been in intimate touch with the various committees and groups that have been attempting during recent years to reform the game so as to remove from it the elements of too great danger. Football films have been studied. The authors realize the danger of the game but feel that it is worth saving, particularly since the average spectator is in greater danger driving to a football game than is a player who plays in it. In their book they consider first training and physical equipment for the game, then the use of physical therapy in treating athletic injuries, next they discuss the various types of injuries and their control. They conclude with a glossary of medical and technical terms and with the results of a careful statistical study of fatalities and injuries. The book is thus exceedingly important for every one interested in the game of football, but particularly for physicians who may be associated with the development and training of athletes. The volume is handsomely illustrated with scenes taken from various films.

Die Brustwandpulsationen als Symptome von Herz und Gefässkrankheiten. Von Dr. Wilhelm Dressler, Assistent der Herzstation in Wien. Cloth. Price 15 marks. Pp. 181 with 87 illustrations. Vienna: Wilhelm Maudrich, 1933.

This publication apparently for the first time assembles in systematic form the many pulsation phenomena observed over the thorax. Observation by simple clinical methods chiefly inspection and palpation are assembled and analyzed with especial reference to their physiologic, diagnostic and therapeutic significance in cardiovascular disease. The isolated observations of pulsation phenomena of the thorax by many of the older clinicians such as Bamberger, Skoda, Ortner and Talma as well as those of the present generation of cardiolo-

gists, are assembled and, in addition, the author has pursued a sensible plan of clinical investigation, using the simple means of ordinary physical examination. This is remarkable in these days of elaborate graphic methods of investigation of cardiovascular disease, which have forced the older although none the less valuable methods of clinical investigation within this field into the background. The volume is carefully planned, well written and adequately illustrated. The first part is a general discussion of the mechanism and interpretation of thoracic pulsations and the second part considers them in reference to special cardiovascular lesions. There is an extensive bibliography listing many of the important older and almost forgotten writings within this field. This book should be of value to all who are interested in the physical examination of patients.

Inherited Abnormalities of the Skin and Its Appendages. By E. A. Cockayne, D.V.M., F.R.C.P., Physician to the Middlesex Hospital. Cloth. Price \$8. Pp. 391 with illustrations. New York & London: Oxford University Press, 1933.

This apparently is the first volume devoted to the importance of heredity in relationship to the development of a single portion of the human body. It constitutes a careful summarization of present knowledge in relationship to the influence of hereditary factors on the development of abnormalities of the skin, teeth, hair or nails. The book, therefore, is a complete guide to most of the extraordinary appearances which fascinate human beings in the sideshows and museums. Beginning with a chapter on the relationship of the mendelian conceptions of inheritance to the special problems affecting the skin, the author takes up physiologic abnormalities and metabolic errors. He then considers errors of development of the elastic tissue, which are of course associated with cases of so called rubber skin and with cases of epidermolysis. He then considers the dyskeratoses and gives special consideration to ichthyosis, or so called fish skin. Thereafter he concerns himself with abnormalities of the nails, the hair and the breasts with unusual disorders of growth and of pigmentation, and finally with conditions of doubtful etiology. He has depended largely for his material on such works as the Treasury of Human Inheritance and various other books in this field. The volume is complete with an excellent index, and there are accurate bibliographic references to all the special considerations appearing in the periodical literature. The illustrations consist primarily of charts showing the order of inheritance of the conditions discussed, but there are also a few plates illustrating unusual appearances. The book should be a most useful work of reference for dermatologists and has at the same time the appeal of interest to every physician.

The New Dentistry: A Phase of Preventive Medicine. Six Lowell Lectures. By Leroy Matthew Simpson Viner, D.M.D., M.D., F.A.C.S., Dean of the Dental School and Professor of Clinical Oral Surgery in Harvard University. Cloth. Price \$2. Pp. 219. Cambridge, Mass.: Harvard University Press, 1933.

This volume consists of six lectures delivered as a Lowell Institute course in 1933. It traces the history of dentistry from the earliest times to the present, analyzing the American contribution, which of course, is the chief contribution in the advancement of this science. Dr. Miner feels that there is no reason why dentistry should not develop, at least for the present, as an oral specialty of medicine. At the same time he does not feel that there is any sufficient reason why the student who proposes to practice dentistry should be obliged to submit to the entire discipline of the medical course before taking up his special dental studies. At the beginning of the nineteenth century there was no dental profession. The development of anesthesia, asepsis, the x-rays and American dental technique have been primarily responsible for its advance. Finally, the emphasis on the conception that the teeth are just a part of the human body cannot be treated separately from an understanding of the body as a whole is fundamental to the practice of modern scientific dentistry. The most recent step has, of course, been the emphasis on diet in relationship to the care of the teeth and on the development of clinics for prophylactic dentistry. In considering the future of dentistry, Dr. Miner feels that the need for dentistry is becoming more acute, since more people are beginning to realize its value. He feels that it must come eventually to complete equality with other medical specialties.

The Ape and the Child: A Study of Environmental Influence Upon Early Behavior By W. A. Kellogg, Associate Professor of Psychology, Indiana University and L. A. Kellogg. Cloth. Price \$3. Pp. 311 with 100 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc. 1933.

The authors of this work undertook in order to study the physiology and psychology of an ape as compared to a child to take into their home a young chimpanzee and to rear it coincidentally with the rearing of a young child. They made careful observations of the ape's habits, its methods of learning and the limitations on its abilities as compared to those of the child, finally bringing forth in their conclusions the advantages in favor of the child, the advantages in favor of the ape and the likenesses between the two. The book is a valuable contribution in the field of comparative psychology and anthropology.

Nahrungsmittel Tabelle zur Aufstellung und Berechnung von Diätverordnungen für Krankenhaus Sanatorium und Praxis Von Dr. Hermann Schall, Leitender Arzt des Kindersanatoriums und des Erholungsheims Westend für Erwachsene, Königsfeld (Badischer Schwarzwald). Tenth edition. Paper. Price 5.40 marks. Pp. 126. Leipzig: Curt Kahlitzsch, 1932.

This is a tabular arrangement now in its tenth edition of all the foods eaten by man with their contents of protein fat, carbohydrates, calories, sodium chloride, purine bases and water, also tables of age, weight and height with caloric requirements, tables of equivalents, vitamins, minerals and similar data. Indeed, one finds here most of the necessary information concerning all the various food substances.

Towards Mental Health: The Schizophrenic Problem By Charles M. Frueh, M.D. Cloth. Price \$1.25. Pp. 110. Cambridge: Harvard University Press, 1933.

These three lectures were the Adolph Gehrman lectures in hygiene at the University of Illinois College of Medicine in 1932. The lectures include a consideration of the general field and special territory, the harmonizing of conflicting trends and questions of heredity and environment. For purposes of publication the author has added a summary. In this summary the author emphasizes the importance of maintaining the well being of the organism not only through attention to its physical aspects but also by adjustment of its conflicting tendencies and encouragement to the attainment of an independent personality.

Psychoanalysis and Medicine: A Study of the Wish to Fall Ill By Karin Stephen, M.A., M.R.C.S., L.R.C.P. Cloth. Price \$2.50. Pp. 238. New York: Macmillan Company; Cambridge, England: University Press, 1933.

This volume is concerned particularly with the wish to fall ill—in other words, the psychologic basis for illness which frequently results in physiologic and pathologic manifestations. The basis for such illness is obviously conflict and repression. The manifestations, however, relate apparently to the sexual nature of the unconscious and to various methods of obtaining pleasure through bodily organs. The concluding chapter deals with defense mechanisms and with the use of transference in treatment.

Grosse Ärzte: Eine Geschichte der Heilkunde in Lebensbildern Von Dr. med. Henry E. Sigerist, Professor an der Johns Hopkins Universität in Baltimore, Maryland. Second edition. Cloth. Price 10 marks. Pp. 316 with 69 illustrations. Munich: J. F. Lehmann, 1933.

This is an enlarged edition of the author's work on famous physicians, in which he gives the biographies of some fifty important medical men from Imhotep to William Osler. The volume is available also in English.

Health and Environment By Edgar Sinden, M.D. Cloth. Price \$2.00. Pp. 217 with 70 illustrations. New York & London: McGraw-Hill Book Company, Inc. 1933.

This volume is a reprint of the chapter on the same subject in the book called *Recent Social Trends in the United States*. It has long been recognized by physicians that climate, nutrition, housing, occupation and similar factors were exceedingly important in relationship to the causation of disease. As a distinguished statistician long associated with the United States Public Health Service, Dr. Sinden has had much opportunity to investigate the definite influences of such factors. So convinced was Dr. Sinden of the importance of such influences that he expressed in his minority opinion on the Report of the Committee on the Costs of Medical Care the view that the report was inadequate because it failed to touch

the basic problems involved. He conceives of all disease as being the result of heredity and environment, and his tendency is to assign far more importance to environment than to heredity in the causation of illness. However, the environmental factors affect chiefly the people in the younger groups and have little effect on those of advanced years.

Medicolegal

Mandamus to Compel Municipal Judge to Enforce Sentence Against Chiropractor—In the municipal court of Toledo in March 1930 twenty-two persons were charged with practicing a limited branch of medicine and surgery—namely, chiropractic—without licenses. One of them, Mueller, was tried and it was agreed that the others would abide by the result of his trial. Mueller was found guilty and sentenced to pay a fine of \$25 and costs. On appeal the court of common pleas reversed the judgment. Eventually Mueller's case came before the Supreme Court of Ohio, where his conviction was affirmed. The judge of the trial court then found all the remaining defendants guilty and sentenced each one to pay a fine of \$25 and costs. Seven other chiropractors were found similarly guilty and sentenced in like manner. The trial court, however, suspended the execution of the sentences that it had imposed. On the petition of the secretary of the state medical board the court of appeals, Lucas County, granted a writ of mandamus directing that the orders of the court below suspending the execution of the sentences be set aside. The defendant chiropractors thereupon appealed to the Supreme Court of Ohio.

We are of the opinion said the Supreme Court that mandamus is the proper remedy by which to compel a court to set aside and vacate an order suspending the execution of a sentence made in a criminal case where the court has exceeded its authority in making the order. There is said the Supreme Court no statutory authority justifying the suspension of the execution of sentences previously imposed by a court on conviction of violation of a state law except as may be necessary to enable the defendants to perfect appeals or to be placed on probation. A municipal court has no inherent authority to suspend the execution of such sentences. The orders made by the municipal court of Toledo suspending the execution of the sentences it had imposed were without authority in the first instance and were therefore void. Being void they could be set aside at any time or stricken from the record and treated as a nullity and the original sentences enforced. The judgment of the court of appeals was therefore affirmed.—*Municipal Court of Toledo v. State ex rel. Platter (Ohio) 184 V. E. 1*

Accident Insurance, Death from Septicemia, Injury and Infection Not Necessarily Simultaneous—This was an action on an insurance policy. The insured accidentally pricked her thumb with a pin Friday, April 18. The puncture caused by the pin remained visible. The soreness increased and the thumb became red. On the Monday following, the injury the insured was unable to work because of the pain in her thumb, and on admission to a hospital it was found that the pain was due to infection. She died on Friday, one week after the day of the accident. Medical testimony tended to show that the germs that caused the infection could not have entered the thumb in the absence of an open sore or wound and that infection and blood poisoning was a natural result of the injury which the insured had received. The insurance policy covered effects resulting directly and exclusively of all other causes from bodily injury sustained through external violent and accidental means. It excluded disability due wholly or in part to disease or bodily infirmity. The trial court directed a verdict in favor of the defendant on the theory that the plaintiff could not recover under the policy because she had not proved that the pin and the germs entered the thumb or the deceased at the same time and that therefore, he had failed to show that death was caused directly and exclusively by accidental means and was not due wholly or partly to disease. The plaintiff appealed to the Supreme Court of Rhode Island.

The Supreme Court quoted with approval from *Delaney v Modern Accident Club*, 121 Iowa 528, 97 N W 91, 63 L R A 603, in which the insured, following a cut on one of his fingers, died from blood poisoning and erysipelas.

It seems to us however that it is wholly immaterial when or how these specific bacilli which caused the disease known as blood poisoning which resulted in the death of Delaney were introduced into the wound whether at the time it was inflicted or subsequently. Blood poisoning is a disease just as many other pathological conditions of the human system. The simple question is whether the death of Delaney resulted through natural causes without the interposition of a new and independent cause from the cut on his finger. Disease brought about as the result of a wound even though not the necessary or probable result yet if it is the natural result of the wound and not of an independent cause is properly attributed to the wound and death resulting from the disease is a death resulting from the wound even though the wound was not in its nature mortal or even dangerous.

The Supreme Court cited also *French v Fidelity & Casualty Co of N Y*, 135 Wis 259, 115 N W 869 17 L R A (N S) 1011, in which the insured died from blood poisoning following an abrasion of the skin on one of his legs. In that case on behalf of the insurer, it was argued that the injury was too slight to cause death and that death was due to an intervening cause, namely the germs which entered the body through the wound. But the court said:

It must be apparent however that but for the accidental injury there would have been no cause for infection but for the abrasion the disease germs could not have entered and produced the fatal result. The wound produced by the accident was therefore the proximate and sole cause of death.

The Supreme Court of Rhode Island therefore sustained the plaintiff's exception to the direction of a verdict in favor of the defendant and remitted the case to the trial court for a new trial—*Pennine v Peerless Casualty Co* (R I) 164 A 32.

Malpractice Negligence in Treatment of Cancer by Escharotics—The plaintiff entered Dr Nichols Sanatorium to be treated for two 'lumps' in her right breast and one in her right axilla. A nurse diagnosed her case as cancer and applied an escharotic mixture containing butter of antimony and zinc chloride. The flesh killed by the applications of this mixture was removed by the nurse, with surgical scissors and a curet. The entire right breast and a large part of the flesh in the axilla were thus removed before the plaintiff left the sanatorium. About fourteen months after leaving she returned for treatment for another lump in her right axilla. The second course of treatment left her right arm useless in the healing process the flesh united her arm to the side of her body and when she attempted to move her arm the scars cracked and bled. At the sanatorium she was told that her condition could not be remedied. She then went to a physician who performed a Wolfe graft operation, which greatly improved her condition. She sued the defendant sanatorium, alleging negligence and unskillfulness. The jury returned a verdict in her favor but the trial court ordered a new trial apparently on the theory that the evidence did not support the verdict. The Kansas City court of appeals affirmed the order of the trial court and the plaintiff appealed to the Supreme Court of Missouri.

There was ample testimony, said the Supreme Court to support the allegations in the plaintiff's petition that the defendant was negligent. If the plaintiff and the physician who performed the graft operation are to be believed the sanatorium discharged the plaintiff in a condition that rendered her practically an invalid for the remainder of her life and that condition could have been prevented or remedied at the sanatorium. There was substantial testimony too that the defendant sanatorium used a method of treatment that had been condemned by the medical profession. Under the evidence, the trial court properly submitted the case to the jury.

In the trial court the defendant sanatorium undertook to introduce the testimony of one of its nurses, to show that no more flesh was removed than was necessary to cure the disease condition. The trial court ruled however that the defendant might show what was done but that it could not introduce as evidence the opinion of this witness as to whether or not more flesh than was necessary was removed because that opinion was a mere conclusion and would invade the province of the jury. On appeal the defendant complained of this ruling. This witness, said the Supreme Court was not qualified as an expert with respect to matters concerning which she was to

testify. Her testimony was properly excluded. The fact that the trial court excluded it on the ground that it would invade the province of the jury, and not on the ground that the witness was not a qualified expert, was immaterial.

The judgment of the trial court awarding a new trial was accordingly reversed, with instructions to restate the verdict of the jury and enter judgment for the plaintiff—*Gates Dr Nichols Sanatorium (Mo)*, 50 S W (2d) 424.

SECOND CONFERENCE ON RHEUMATIC DISEASES

Held under Sponsorship of the American Committee for the Control of Rheumatism Milwaukee June 12 1913

Degenerative (Hypertrophic) Arthritis

DRS CHESTER S KEEFER and WALTER K MYERS Boston
Our observations on anatomic changes in the knee joints show that degenerative (hypertrophic) arthritis increases with advancing age. What is true of the knee joint also applies to other movable joints of the body. Aside from age, other factors such as occupation gross injury to joint surfaces and static deformities influence the prevalence of degenerative arthritis. The anatomic alterations in the tissues can be explained on a basis of injury to the cartilage and bone which follows wear and tear of joint structures and an attempt on the part of the tissues to repair the injury.

DISCUSSION

DR J A KEY St Louis I agree with the authors conclusions concerning the incidence of chronic arthritis in later life. The anatomic signs of degenerative (hypertrophic) arthritis are degeneration and erosion of cartilage and formation of osteophytes. Does this wearing out of a joint render it vulnerable so that it may become sore and painful? Many badly worn joints are not painful and other joints with relatively slight changes in bone are so painful that the patient walks with difficulty. Hypertrophic changes may be present in a joint for years and the patient never know it until some physician puts his hand on the crepitating knee and says: Hear that? You have rheumatism. There must be alterations besides those in cartilage and bone. Did Dr Keefer and Dr Myers study the synovial tissues also?

DR RUSSELL A HADEN Cleveland I wish to know what the authors think of infection and other agents as accelerating factors in this disease.

DR RALPH PEMBERTON Philadelphia Dr Goldhaft and I have been carrying out studies on the influence of ligation of patellar vessels in young and old dogs and have noticed apparently marked differences in the two groups. Whereas in older dogs changes develop that are rather characteristic of

hypertrophic arthritis, in younger dogs much less overgrowth develops, sometimes none. This seems to corroborate the views of some observers to the effect that the kind of response which the tissues yield is conditioned, at least in part by the age of those tissues.

DR C S KEEFER, Boston. We are all interested in what produces symptoms in cases of degenerative (hypertrophic) arthritis. Only about 7 per cent of the patients complained of any pain referable to the joints; we too have looked for factors other than anatomic changes in an attempt to explain symptoms. In some cases infarcts in synovial tissue may produce hemorrhage and cause pain but I cannot say why many patients with extensive changes have no pain. We studied the synovial tissue in all these cases; in 65 per cent it glistened with smooth layers of cells without evidence of inflammation. In some cases we found thickening and hypertrophy of synovia with perivascular round cell reaction. This may be evidence of inflammation and it may or may not play a part in producing symptoms referable to the joints. There is no doubt that accelerating factors play an important part in determining the final changes in joints. Age, infection, gross and occupational trauma, hemorrhage, and static defects are of the highest importance. We have not been able to find any correlation between the degree of arteriosclerosis present and the extent of the anatomic changes. We have frequently found advanced arteriosclerosis of the blood vessels about the joints and few anatomic changes. In other cases, extensive alterations in the bone and cartilage are seen with normal blood vessels.

Joint Tissue Changes in Chronic Atrophic (Rheumatoid) Arthritis

DR R K GHORMLEY, Rochester, Minn. From the standpoint of pathology, the nomenclature of Nichols and Richardson is more satisfactory than any other terminology. Much more effort should be made to study pathologic material in cases of arthritis. In a study of pathologic changes in joints, attention must be given to three aspects: changes in synovial membrane, in cartilage and in bone. The changes in synovial membrane are those most often studied for these tissues are more easily obtained. It is seldom possible to obtain bone or cartilage. All are familiar with the thickening of the synovial membrane and the formation of villi or overlapping folds. The folds are filled with cells of two main types: fibroblasts or young connective tissue cells and lymphocytes or small round cells. Later, if circulation becomes established, definite new blood vessels are seen. These blood vessels however seldom have thickened walls. The small round cells are collected in nests, in some of which are central areas composed of larger cells which at times contain mitotic figures. In many ways these suggest a specific reaction of local cells to some outside stimulus.

The cartilage is overgrown and invaded by a pannus from the synovial membrane. Coincidentally subchondral invasion takes place probably from bone marrow. These two processes going on simultaneously ultimately produce extensive destruction of cartilage. If this destruction has gone on to the extent that bare cancellous bone comes in contact with cancellous bone, ankylosis usually occurs. The changes in bone are less well recognized because bone is very difficult to obtain in these cases except when joints are resected and they seldom are resected in the early stages. However one may see these changes in bone marrow—that is, collections of small round cells in foci. Atrophy of trabeculae also takes place to a variable degree.

DISCUSSION

DR R A KINSELLA, St. Louis. Dr Ghormley's work goes considerably further than that of Nichols and Richardson. Here is evidence tending to corroborate the old idea that arthritis deformans and rheumatic fever are related diseases. If the microscopic picture Dr Ghormley presented in cases of atrophic arthritis were compared with that of lesions in other parts of the body in acute rheumatic fever, the resemblance would be striking.

DR M H DAWSON, New York. I have recently examined tissues from several patients with early atrophic (rheumatoid) arthritis and invariably found the changes Dr Ghormley has described. I have also examined sections of synovial tissue from patients with orthodox rheumatic fever and have found

remarkable similarity in the lesions in the two diseases. In certain instances it is practically impossible to tell the lesions apart.

DR L D SMITH, Milwaukee. Did Dr Ghormley frequently find semifluid, necrotic material in those knees?

DR J A KEY, St. Louis. It is interesting to see in what respects the pathologic changes in rheumatoid arthritis are comparable to those in tuberculous arthritis. The fact that tuberculous, pyogenic and gonorrheal arthritis are all known to be infectious diseases argues strongly for the infectious nature of other forms of chronic arthritis. Although I have been unable to confirm the work of those who obtained bacteria by culture, either from blood or from joints in chronic arthritis, I cannot get away from the idea that it is an infectious disease because the pathologic changes resemble somewhat those of known infections in joints. For years I have searched sections stained for bacteria but never have found them. Did Dr Ghormley make a search for bacteria?

DR R K GHORMLEY, Rochester, Minn. I am much interested in the statements regarding the changes in rheumatic fever. We had no such cases. We had very little success in demonstrating organisms in the joints. Dr Zinsser examined many of these joints but found no pathologic organisms. But what is an infection of joints? Is it the effect of bacteria in the joint itself or is it the chemical changes resulting from bacterial growth elsewhere producing changes in joints? That cannot be touched on until more is known about the chemistry of the process.

Physiology of Normal Joints as Related to Rheumatoid (Atrophic) Arthritis

DR WALTER BAUER, Boston. In our clinic we have continued studies on anatomy and physiology of normal joints, believing that more complete knowledge of the normal eventually will lead to better understanding of how the proliferative changes of rheumatoid (atrophic) arthritis are brought about. These studies are of necessity being carried out on animals. As a result of cytologic and chemical studies on synovial fluid obtained from young cattle we can define normal synovial fluid with some degree of certainty. It contains on an average 132 nucleated cells. Erythrocytes are not present. Comparison of the concentration of certain nonelectrolytes in synovial fluid and arterial blood shows that they are practically identical. For this reason and others based on data obtained from this study, we believe that synovial fluid is probably a simple diffusate coming from the rich subsynovial blood supply.

In order to obtain information relative to the interchange of fluids in joints we determined the manner of removal of proteins from joints of dogs. The proteins contained in egg white and horse serum were removed only by way of the lymphatic channels and more rapidly if the joints were passively exercised. The smaller molecule horse serum albumin was readily removed from a normal dog's knee joint, whereas the larger molecule horse serum globulin, escaped with difficulty, if at all, and therefore did not readily gain entrance into the subsynovial lymphatic capillaries. Such information should add to our understanding of the mechanism of effusions in joints. An effusion can result from too rapid formation of synovial fluid from interference with removal of proteins or from a combination of the two. Application of this knowledge is being made in the clinic and undoubtedly will aid in understanding and treating disease of the joint.

DISCUSSION

DR J A KEY, St. Louis. When an effusion occurs in a joint there is a change in the synovial membrane accompanied by blockade in absorption from the joint. A similar blockade accompanies pleurisy. I hope to conclude experiments to determine the rate of absorption from joints in which a low grade synovitis had been produced. Has Dr Bauer done this?

DR WALTER BAUER, Boston. Dr Key is a jump ahead of us. We have wanted to do such work but time has not permitted. At present my associates and I are carrying out experiments with joint effusions in an effort to determine which of three factors is at fault: (1) increased formation of synovial fluid, (2) interference with lymphatic drainage or (3) a combination of the two.

Studies on Rheumatoid Arthritis

DRS M H DAWSON and R H BOOTS, New York. It is our belief that rheumatoid (atrophic) arthritis and osteo arthritis (hypertrophic arthritis) represent two distinct processes, entirely diverse in etiology, possessing little if anything in common in pathologic anatomy, demanding a widely different therapeutic approach, and resembling each other in the single characteristic that both disorders primarily involve the structures of the joints. Contrary to the results of other investigators, we have not been able to recover streptococci from the blood or tissues of patients with rheumatoid arthritis. Serum from 321 patients with rheumatoid arthritis, and from 371 controls, have been examined. Agglutination reactions with living coccal organisms must always be done at a temperature which kills the organisms, that is approximately 55 C. If heat-killed organisms are employed, a temperature of 37 C is permissible but agglutination reactions with living coccal forms at 37 C are entirely without significance. Usually the serum from patients with rheumatoid arthritis agglutinates hemolytic streptococci in high titers but does not agglutinate other organisms in any significant titer. Serum from controls and from patients with osteo arthritis does not give positive agglutination.

Precipitin tests carried out with both protein and carbohydrate fractions of *Streptococcus haemolyticus*, serum from 100 patients with rheumatoid arthritis being used and 600 controls suggested that both the agglutination and precipitation reactions are specific. More than 2,000 observations on the sedimentation rate of erythrocytes of several hundred patients were made. In rheumatoid arthritis the rate paralleled to an extraordinary degree the severity and extent of the arthritic process. In active cases it was usually greatly elevated generally more than 30 mm in an hour. The test offered a convenient method of evaluating the results of therapeutic measures and was useful as an aid in distinguishing rheumatoid arthritis from osteo-arthritis. The rate was normal in cases of myositis neuritis and fibrositis.

During the last four years several hundred patients with rheumatoid arthritis have been treated with small and large doses of different vaccines variously administered: autogenous vaccine subcutaneously, streptococcus antigens, typhoid vaccines, and vaccines from strains of streptococci subcutaneously and intravenously. It is our belief that the value of vaccine therapy in the treatment of rheumatoid arthritis has not been proved. The sedimentation rates are not favorably influenced and patients on other treatment than vaccines improve equally well. There seems to us no justification for the use of vaccines as a routine in the treatment of osteo-arthritis. Immunologic evidence confirms the clinical impression that rheumatoid arthritis is a clinical entity and suggests that it is associated with infection by *Streptococcus haemolyticus*.

DISCUSSION

DR MACNIDER WETHERBY, Minneapolis. It is difficult to ignore the significance of the isolation of streptococci from the blood cultured from hundreds of patients with chronic arthritis by such investigators as Moon and Edwards, Richards, Hadjopoulos and Burbank, Cecil, Nichols and Stainsby, Klugh, Gray and Gowan, Clawson and Wetherby, Straus, Ashworth and Traut. A number of these investigators have found streptococci in the blood of 50 per cent or more of patients and have run 'blindfold control' cultures with negative results. It is also true that others including Nye and Wavelbaum, Bernhardt and Hensch, and Dawson, Olmsted and Boots have not found streptococci in blood cultures, however, it seems not unlikely that minor differences in technique might account for such negative results. There have likewise been a number of reports of the isolation of streptococci from joint fluid, joint tissues, regional lymph nodes and subcutaneous nodules in chronic arthritis. The organisms found have chiefly been classified as *Streptococcus viridans* with respect to their effect on blood agar. There has also been evidence tending to show that diphtheroid organisms isolated may often represent pleomorphic forms of streptococci. Cecil and his co-workers, however, have termed the organism most frequently isolated an atypical hemolytic strain although they have classified some as *Streptococcus viridans*. Cecil sent us one of his isolated strains which he considered an atypical hemolytic strain. Following Brown's

classification of streptococci in blood agar Cecil's A B 13 strain might be termed "alpha prime." Most of the strains isolated by us from either the blood or subcutaneous nodules would be classified as viridans or alpha, although a few would be classified as alpha prime, and in a few cases as true beta strains. The results from culture have seemed of greater etiologic significance than have been results from agglutination tests. Dawson and Boots have presented data in their agglutination and precipitin tests tending to show in blood from patients with chronic arthritis an elevation of agglutination titers with hemolytic streptococci. They have not found much agglutination proper against *Streptococcus viridans*. It may be that the strains of viridans used were not as sensitive to agglutination as were the hemolytic strains. Clawson and I have run many hundreds of agglutination tests on controls and on children with rheumatic fever, on adults with chronic arthritis, and on patients with chronic glomerulonephritis and scarlet fever. We have used two strains, Cecil's A B 13 (from the blood of a patient with chronic arthritis) and a strain of *Streptococcus viridans* (alpha) which was isolated by Clawson from the blood of a patient with chronic rheumatic fever and pericarditis. The strain of viridans which we have used is sensitive to agglutination and, in our series, testing agglutination with these two strains, we have found that the blood from patients with clinical rheumatic fever and chronic arthritis ran a moderately higher range than that from normal controls but that our patients with glomerulonephritis and scarlet fever ran much higher titers than any of the other groups. We were unable to find any evidence for specificity of strain. Animals that have been immunized with intravenous injections of this strain of viridans, so that the agglutination titer of their blood was significantly raised, have likewise agglutinated Cecil's strain A B 13 at a very high level. We do not believe that the action of a streptococcus on blood agar necessarily places that strain in a sharp biologic group. There is no doubt that minor technical differences greatly influence agglutination determinations in different laboratories. We have not found that the temperature of the water bath at 55 C has given any more specific results than when run at 40 C, with living organisms, but we have found that the dilution of the suspension is of great importance in influencing the dilution in which agglutination was demonstrable at either temperature with these two strains. We have been unable to place the majority of our patients in such distinct groups as rheumatoid arthritis and osteo arthritis, on a clinical, bacteriologic, pathologic or roentgenologic basis, and we share the view of McRae, Rolleston and Timbrell Fisher on that point. It is to be hoped that at some future time a greater effort will be made to use an etiologic terminology for disease of joints, possibly using such terms as streptococcic, gonococcic and tuberculous arthritis, and traumatic and senescent diseases of the joints. We have at present about 1,500 patients with chronic arthritis who have received streptococcus vaccine intravenously. About 80 per cent of such patients have believed themselves definitely benefited within a few months after beginning treatment, experiencing decrease in pain and swelling, and increase in motion of joints. There are of course definite limitations placed on possible benefits from vaccine therapy in cases in which severe permanent injury of joint tissues has taken place. One must be most careful in evaluating results in such a disease as chronic arthritis with its periods of spontaneous remission and exacerbation. The clinical results, however, have seemed too encouraging to be explained by chance or by overenthusiasm. Based on Clawson's experimental work on animals we do not believe that subcutaneous or intramuscular vaccination is comparable with vaccination by the intravenous route.

DR J L MILLER, Chicago. Did the authors make agglutination tests on patients with infectious spondylitis? Fischer has reported a number of these cases in which the patient also had rheumatoid arthritis affecting the extremities. He expressed the belief that infectious arthritis is rheumatoid arthritis of the spine.

DR M H DAWSON, New York. We have felt that infectious spondylitis is simply a variety of rheumatoid arthritis. May I ask Dr Wetherby whether his agglutination tests were done at 37 or at 55 C. In our experience that makes a very considerable difference.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Primary Tumors of the Liver—Brines encountered eight cases of primary carcinoma of the liver in 1087 consecutive necropsies. Six of these were hepatomas and two cholangiomas. The patients were the type usually encountered in a charity hospital. Alcoholism and syphilis appear to play a minor etiologic part. While cirrhosis was associated with only one of these cases (a hepatoma) the author makes no attempt to dispute the reported relationship between cirrhosis and primary carcinoma of the liver in the experience of others. The two cases of secondary melanoma of the liver illustrate that probably most primary melanomas of the liver which have been reported are only apparently primary there. He believes that diagnoses of primary sarcoma of the liver should be viewed with suspicion on the ground that many so diagnosed are of epithelial origin. A much higher percentage of primary carcinoma of the liver is apparently found in necropsies on patients in whom chronic hepatic diseases are prevalent. The gross appearance of hepatomas is not especially helpful in identifying the lesion but the histopathologic picture is fairly distinctive and a positive microscopic diagnosis can usually be made.

Acute Pyogenic Phlebitis—Neuhoef states that because phlebitis associated with general surgical infections spreads rapidly and often results in death from septicemia, the indication for operation is urgent. An operative treatment for pyogenic phlebitis complicated by general septic invasion must be based on a plan for complete elimination of that focus. Proximal ligation of the vein should be considered a temporizing method. The technic of operation is based essentially on liberal exposure of the vein at the site of phlebitis or suspected phlebitis. Special attention should be given to adequate exposure proximal to the end of the lesion, because excision is to be performed beyond the limits of the phlebitis. Either a serrefine or a temporary ligature is placed on the proximal portion of the vein before dissection of the vein is carried out. A plane of cleavage between the vein and the surrounding tissues can always be found and the microscopic alterations in the vein do not extend far beyond the visible and palpable site of the lesion. When phlebitis without evident thrombosis is encountered the microscopic examination reveals a diffused infection of the wall of the vein with minimal or no thrombosis. Infection may be present to the same degree when the vein appears normal as at the site of visible phlebitis. Excision or incision or any other effort at immediate elimination of the focus cannot be advocated in the treatment of phlebitis without thrombosis.

Multiple Myeloma—Caylor and Nickel present data concerning a patient afflicted with multiple myeloma which in many respects simulated hyperparathyroidism. The correct diagnosis was made after biopsy. The authors believe that occasionally neoplastic diseases may be associated with a hypercalcemia although hypocalcemia is the rule. Their observations and those of Mason and Shields suggest that when a hypercalcemia and malignant disease coexist the phosphorus content of the blood serum is within the normal limits. From their study it would seem that the phosphorus content of the blood serum in hyperparathyroidism is of equal importance with the calcium content.

Skin Conservation in Mastectomy—According to Friedman an ideal breast incision for carcinoma should permit easy access to the axillary space so that thorough removal of axillary lymph nodes and fat can be accomplished. It should permit closure of the wound without undue tension without the necessity of skin grafting or of a granulating area and it should leave a fairly presentable linear scar. This can be accomplished by conserving and utilizing the skin covering the breast farthest away from the tumor depending on its size and location. Dividing the breast into quadrants since tumors can be so classified the skin is to be conserved by dissecting it off the side of the breast not containing the mass, thereby the amount of integument girded will be from 2 to 3 inches in width extending the entire half of the diameter of the breast and the closure of the wound will be much more easily obtained with the least degree of tension. In many instances the outline of the skin incision can be carried up to the areola or the nipple but it should never include the nipple or its areola particularly

when there is nipple retraction. By gaining from $2\frac{1}{2}$ to 3 inches of skin area, it will not be necessary to undermine the skin beyond the circumference of the breast. Even in cases presenting a comparatively large tumor mass a considerable area of the skin can be safely dissected off the normal side of the breast. Retention sutures are usually not required.

Primary Jejunal Ulcer—Ebeling points out that the recognition of simple ulceration of the jejunum depends on the history of dyspepsia and gastric distress with symptoms not unlike those of peptic duodenal ulcer and occasionally, of subacute obstruction of the upper part of the jejunum. The location of the ulceration may be determined by serial roentgen studies of the gastro-intestinal tract. The majority of primary jejunal ulcers manifest themselves by acute perforation. The diagnosis of perforated ulcer of the jejunum may be made from the history of a sudden onset of pain with fulminating signs and symptoms of peritonitis, whether or not there is a previous history of ulcer. The use of the roentgenoscope is recommended for its value in the demonstration of air under the dome of the diaphragm in the presence of a perforated jejunal ulcer as it is for a similar perforation of a duodenal or gastric ulcer. The mortality may be lowered by early surgical intervention. Pain or obstructive symptoms with localization of the lesion to the jejunum should be treated surgically.

Congestive Heart Failure and Angina Pectoris—Blumgart and his associates give reasons for believing that patients with a normal metabolism who suffer from congestive heart failure or angina pectoris might show striking improvement if the metabolic rate were significantly lowered. The hearts of such people might be unable to supply enough blood for the ordinary demands of a normal metabolic rate but nevertheless might be able to supply enough blood for a reduced metabolic rate. The authors report the results of producing a subnormal metabolic rate by thyroidectomy on three patients who were suffering from severe congestive heart failure but who showed no evidences of disturbed thyroid function, and on one patient with angina pectoris with a slight elevation of metabolism but with a normal gland. In two of the three patients with severe congestive heart failure subtotal thyroidectomy caused a fall in the metabolic rate which reached its minimum about three weeks after operation. The basal metabolic rates in these two patients again rose toward the preoperative normal level and their clinical conditions became less favorable. One of these patients continued for an additional month to show a somewhat lessened metabolic rate than before operation and his clinical condition while not as good as that

three weeks following operation, was definitely better than before operation. The patient suffering from angina pectoris has shown no recurrence of the attacks since subtotal thyroidectomy, although he has returned to work and active life. Before operation attacks of angina pectoris occurred even while he was at rest. In one patient with congestive heart failure complete ablation of all thyroid tissue was done the parathyroids being spared. This patient has maintained clinical improvement, and the metabolic rate has remained persistently lowered for more than six weeks. The procedure should be employed only in carefully selected cases in which all known therapeutic measures have proved ineffectual.

Histamine Test Meals—Pollard made an analysis of 988 consecutive histamine test meals. Of these patients 684 showed no evidence of disease, and standards of normal for gastric acidity and volume of secretion were derived from these data. The mean total acidity for men ranged from 101.1 units at the age of 25 to 67.1 units at the age of 65, and for women from 82.2 units at the age of 25 to 66.7 units at the age of 65. This included normal subjects who had anacidity. There was a definite correlation between age and acidity in men. The mean maximum ten minute volume of secretion for men ranged from 39.7 cc at the age of 25 to 24.9 cc at the age of 65. The mean volume of secretion for women ranged from 33.1 cc at the age of 25 to 21.7 cc at the age of 65. There was a definite correlation between age and volume in the two sexes. The total gastric secretion declined with age at about the same rate. There was a steady increase in the incidence of anacidity from youth to old age and at all age periods up to 60 the incidence was higher in women than in men. The incidence for the normal man was 10.7 and for the normal woman 14.1 per cent. In 130 cases of duodenal ulcer, 91.3 per cent of the patients had a total acidity and 79.2 per cent had volumes of secretion higher than the mean values of normal persons of the same age and sex. In 36 cases of gastric ulcer, 91.7 per cent of the patients had a total acidity and 75 per cent had volumes of secretion higher than the mean values of normal people of the same age and sex. In 56 cases of carcinoma of the stomach the incidence of anacidity was 69.6 per cent, only 1 patient had an acidity and 3 had volumes above the mean normal value for the same age and sex. Of the male patients with gastric ulcer and duodenal ulcer 87.1 and 92.5 per cent, respectively, had total secretions above the normal mean for age and 100 per cent of the male patients with carcinomas had total secretions below this mean. The author discusses the diagnostic value of the histamine test meal in differentiating benign from malignant lesions of the stomach. In a miscellaneous group of cases no evidence could be found that any particular disease, except pernicious anemia, was associated with a characteristic type of gastric secretion.

Auricular Flutter—Parsonnet and Parent report a case of auricular flutter with an unusually high auricular rate. This condition was superimposed over a complete dissociation of the auricles and ventricles in a patient who subsequently died with all the classic manifestations of coronary occlusion and infarction. Of singular interest was the rarity of such a combination of abnormal rhythms, the extremely high auricular rate, the rapid changes of axis in the various leads, the clear demonstration of flutter configuration in lead I and finally the typical T waves as seen in coronary disturbances.

Standardization of Chest Leads—Hoffman and Delong believe that uniform tracings can be secured in normal patients when the electrode is placed in the following positions. The respective anterior and posterior positions of the electrode in position A are in the center of the chest at the level of the fifth to the sixth interspace and in the center of the back on a level with the anterior electrode. In position B, over the position of the maximum impulse of the heart and on the left side of the spine between it and the scapula at the level of the spine of the scapula. In position C on the left side of the chest over the second interspace about 2 to 3 inches from the midsternal line and at the same posterior site as in position B. In position D over the position of the maximum impulse and on the left side of the back below the angle of the scapula on a level with the anterior electrode and in position E in the center over the precordia and on the left side of the back on a level with the anterior electrode. The authors employed these posi-

tions in obtaining electrocardiographic tracings in a series of 125 normal control cases and in a series of clinical cases of coronary thrombosis and other forms of myocardial damage. They state that by uniform technique and with care as to the position of the electrodes uniformly normal tracings can be secured on patients with normal hearts. In no instances did they obtain other results and only in diseased hearts did they obtain abnormal chest leads. The changes found in diseased hearts were not limited to patients with coronary thrombosis. These changes occurred in such patients in whom standard leads were either normal or abnormal. Apparently the changes in lead IV occurred at times before abnormalities arose in the standard leads. Frequently they reverted to normal before the abnormalities of the standard lead had done so. In a few instances they remained for many months presumably as evidence of residual myocardial damage long after the standard leads had become normal. In a small group with characteristic changes of coronary thrombosis in the standard leads, no abnormalities in the chest lead were noted. Abnormal chest leads were found in two instances of rheumatic heart disease with mitral stenosis (both with normal standard leads), and in one patient with syphilitic heart disease. The latter had normal standard leads. None of these patients had evidence of coronary disease post mortem. In one of the rheumatic hearts there was considerable adhesive pericarditis.

Tumors of the Suprarenal.—Geschickter states that the cortical tumors of the suprarenals arise from small islands of undifferentiated mesenchymal tissue related in origin to the sex glands. These small embryonal islands can be found in normal suprarenals in the region of the capsule. When slowly proliferating these cells give rise to the benign cortical adenomas without marked clinical symptoms. When more rapidly proliferating they give rise to cortical carcinomas with clinical changes in the sexual characteristics of the patient. The medullary tumors of the suprarenals are of the nature of sympathetic nerve tissue or of chromaffin tissue both of which have a common origin in undifferentiated neurogenic tissue of the sympathetic type. The more slowly growing sympathetic nerve tumors give rise to ganglioneuromas or ganglionic sarcomas. The chromaffin tissue gives rise to chromaffin cell carcinomas and to paragangliomas. The more undifferentiated neurogenic tissue gives rise in childhood to the malignant sympathoblastomas and in adult life to the malignant sympathetic neuroblastomas. The neurogenic tumors may arise from undifferentiated cells of the suprarenal medulla or from outlying ganglions of the sympathetic nerves that supply this organ. The author presents an outline indicating the relation of these tumors.

Blood Diastase in Cancer.—Tureen determined the diastase content of the blood at various times during the course of the illness in eighty-one patients with malignant disease. Marked fluctuations of the diastase level in individual patients could be observed at different times. Twenty-one of the patients had low blood diastase when first examined. Five of these subsequently had a normal diastase value and sixteen or 78 per cent of those with low diastase died or were in a poor state of health. Fifty-four were found to have a normal content of diastase in the blood when they were first examined. Eight subsequently had a low blood diastase. About one-half of the patients with a normal content of diastase in the blood subsequently died or were in an unsatisfactory state of health at

the time of this report. Five patients had high blood diastase. Two of them had obstruction of the pancreatic duct, and in two the determinations were made shortly after radiation therapy. All these patients had died or were hopelessly ill subsequent to the time they were studied. A definite increase in the blood diastase was observed shortly after radiation therapy. This increase followed a latent period of some days during which no noticeable change in the diastase content of the blood could be detected. After an interval of from one to four weeks the blood diastase became normal in amount.

Acute Intestinal Obstruction.—Wangenstein treated twelve patients with simple acute mechanical intestinal obstruction by suction siphonage through the nasal catheter. Decompression was unsuccessful in an early case by this method because the catheter did not enter the duodenum. In another decompression was successfully effected by suction but recurred sixteen days later. The distention of the small intestine was again satisfactorily dealt with by suction by nasal catheter, but attempts at feeding the patient resulted in increasing distention. Enterostomy was done to permit of feeding. In nine instances, a satisfactory decompression was obtained by suction alone. In another also decompressed by suction in which the obstruction continued the patient unfortunately died following an ill advised attempt to ascertain the nature of the obstruction and reestablish the continuity of the intestine. The method has also been successfully used in a number of instances of subacute and chronic obstructions, due chiefly to narrowing of the pelvic colon and rectum by carcinoma of the pelvic genital organs of the female. Through relief of the obstruction by nasal and rectal suction in such instances and subsequent regulation of the diet and administration of liquid petrolatum many such patients have been spared a terminal colostomy. Suction by nasal catheter has been employed also as an auxiliary aid in the relief of distention following the release of obstructions of strangulation. Only under unusual circumstances such as gangrene or the greater length of the small intestine is a primary anastomosis to be done. The prohibitive mortality of doing a resection with anastomosis in the presence of devitalized intestine is well illustrated in strangulated external hernias. The devitalized segment should be brought out through the incision and on completion of the closure the dead intestine should be cut off and a catheter tied into each loop.

***Aspergillus Fumigatus* Sinus Infection.**—Adams reports a case of fungus infection in a woman due to *Aspergillus fumigatus* involving not only the maxillary sinus but the ethmoid, sphenoid and orbit. In the three proved cases of *Aspergillus fumigatus* infection reported in the literature the maxillary sinus alone was involved. It is of interest to note that in the eight previously reported cases of fungus

infection of the sinuses seven were in women in one the sex was not mentioned. The mode of infection is not definitely known. The course of the disease is slow and progressive. In the present case the disease probably existed unrecognized for six years. Clinically, the symptoms are those of a chronic suppurative sinusitis with toxic manifestations. The disease may easily be confounded with an ordinary chronic suppurative sinusitis, mucocoele and new growth. Only by careful biologic and pathologic studies can a definite diagnosis be made. The treatment found efficacious in this case was the internal administration of large quantities of a saturated solution of potassium iodide and thorough surgical removal of the growth. After one year the patient was free from symptoms, and there has been no recurrence.

Unilateral Spine Fusion—Klemberg describes a simplified technic for unilateral spine fusion in which a vertical incision is made from the tenth dorsal to the third lumbar spinous process. The incision is extended through the superficial and deep fascia immediately bringing into view the spinous processes. With a thin chisel the eleventh dorsal spinous process is split in an anteroposterior direction; the left half is left attached to the vertebra while the right half is split off from the lamina near its base. A periosteal elevator is inserted under the split off half of the process and the process and the periosteum on the right side of the arch are elevated from the underlying bone to the articulation. The interspinous ligament is cut through in an anteroposterior direction and the right half is retracted outward with a periosteal elevator. The same procedure is carried out on the other spinous processes and the interspinous ligaments. The laminae on the right side of the vertebrae are exposed. Under this thick layer of tissue a graft of beef bone is placed on the laminae near the articulations. Frequently, before placement of the graft chips of bone are removed from the laminae and placed across the interlaminae spaces. The sheet of muscle, bone and periosteum is then mobilized by two incisions through it one at each extremity. With gentle traction the split portions of the spinous processes are brought into the interspinous areas and into contact with the unsplit segments. They are held in place with interrupted strong number 3 or 4 chromicized catgut sutures passed through the strong fibroperiosteal covering on the spinous processes. The wound is closed with a layer of catgut sutures for the deep fascia and another for the superficial fascia and a layer of silk sutures for the skin. The author believes that this procedure of unilateral spine fusion permits thorough preparation of the vertebrae for fusion without removal of the bony support of the spinous processes. Union of the spinous processes is assured by bringing them with segments of their own substance. The time of operation is relatively short. The manipulation should be gentle. This operation may be employed in patients of advanced age, and also in those who are debilitated and too sick to be subjected to prolonged anesthesia and severe operative procedures.

Operations for Incontinence of Urine and Feces—Price presents a case of incontinence of feces and urine due to defective innervation. The operation of Wreden successfully controlled the anal incontinence. In order to relieve the incontinence of urine a method was devised which utilizes bodily posture to tighten or relax a strip of fascia slung about the urethra. In this case it has resulted in voluntary control of the bladder. The results of the two operations after a period of over a year have been satisfactory. The author gives the details of the second operation.

Natural Avoidance of Conception—Anderson contends that a permanent record of menstruation and ovulation should be kept by every woman. The majority of women can be taught to know when they ovulate. The process of ovulation normally

goes on in a regular cyclic or rhythmic succession. Ovulation always occurs twelve to sixteen days preceding the next menstruation. The unmated egg cell retains germinating ability only for about twenty-four hours after it leaves the ovary. The sperm lose their power to fertilize the ovum after two to three days in the female genital tract. The motility of sperm is no indication of its power to fecundate. On these facts the Ogmo-Knaus theory expounded by Latz is based. The theory in brief is that the period during which the woman is apt to be fecundated does not exceed seven or eight days before ovulation and two or three days for the life of sperm.

Test for Liver Function During Pregnancy—Soffer performed a total of thirty-one bilirubin tests in order to determine the liver function of twenty-one normal pregnant women during the various phases of gestation. Eleven of the patients were observed during the first four months of pregnancy, and only one showed an abnormal response to the injected pigment. Of the ten patients studied during the last five months of pregnancy, all but one yielded abnormal results. Ten patients were investigated during both the first and the second half of pregnancy. Only two of these failed to show an increase of injected bilirubin after four hours while one patient during the first half of pregnancy, showed an abnormal retention which was increased slightly in the second half. There seemed to be no relationship between the vomiting that occurs in the early part of pregnancy and the disturbed liver function in the later period. That the impairment is not a permanent feature is evidenced by the fact that those women who had gone through multiple pregnancies before the present study failed to show any increase in the retention of injected bilirubin during the first four months of gestation.

Morquio's Disease—Barnett relates the histories of two sisters having Morquio's disease. He thinks that all children suffering from this disease are members of one peculiar family or race. The children are short the eyes are widely separated, the nose is depressed the neck is short the sternum is so pushed and bent forward that it appears as a shelf on which the chin rests the spine is kyphotic the hips are flexed so that the children appear to crouch the hands extend almost to the markedly knocked knees the feet are kept apart and the ends of the long bones are prominent. That these cases present a clinical entity is evident. The familial tendency is also quite evident. The deformities are almost identical and yet are different from other classified types of hereditary deforming cartilaginous or osseous dystrophies.

Icterus Neonatorum—The study of Gordon and Kemelhor of the icterus index in relation to the number hemoglobin content and fragility of the red blood cells in the peripheral blood of thirty new born infants shows the following: 1 The icterus index during the first ten days of life shows higher values than at any other period under normal conditions. There is a rise and then a fall, the peak being reached on the sixth day. 2 The red blood cells show an initial polycythemia with a subsequent continuous drop in the first six days which is followed by an upward trend. The figures on the tenth day are below those of the second. 3 The hemoglobin content parallels the red blood cell count in both initial values and subsequent fall. 4 There is an initial increased fragility of the erythrocytes to saline solution, which diminishes and tends to approach normal figures on the tenth day. 5 Manifest jaundice was present in twenty-five of the thirty infants. The greatest degree of jaundice was observed in the first six days. Every new-born infant has jaundice, either latent or manifest. 6 A definite relationship exists between the icterus index and the values of the erythrocytes and hemoglobin. The index rises and the other two components fall in the first six days but the index falls in the latter part of the week irrespective of a rise or fall in the other two elements. 7 Manifest jaundice is most intense at the time of the greatest loss of erythrocytes and of the hemoglobin content of increased fragility and of highest icterus index. 8 All these conditions point to the hemolytic origin of icterus neonatorum.

Incontinence in Children—From a study of 250 cases of incontinence (mostly nocturnal enuresis), Beverly states that incontinence is but one of many symptoms in every case. It is but one manifestation of a disturbance of general behavior. Children remain infantile or return to their infancy when growing up becomes too difficult, the incontinence being one symptom of the infantilism. The factors causing the incontinence include any innate characteristic or environmental condition that makes growing up and taking on responsibility too difficult. The causative factors may be superficial or include deep seated personality disorders. The treatment consists in teaching the patient responsibility, psychotherapy and adjustment of environmental conditions. It is more important to treat the underlying maladjustment than the symptom.

*Stimulation of Coronary Thrombosis by Angina Pectoris Induced by Paroxysmal Tachycardia: Two Case Reports J Sproull, Haverhill, Mass—p 1198

Angina Pectoris and Asthma—According to Wolff, angina pectoris (or status anginosus) and cardiac asthma may be induced by paroxysmal auricular fibrillation and paroxysmal tachycardia. The condition constitutes a distinct group which should be differentiated from all other cases of angina pectoris. The pain begins with or soon after the onset and ends with the termination of the arrhythmia. Nitrites are usually ineffective and are better not administered. Morphine is indicated except in the short attacks. Quinidine sulphate is effective in preventing or curtailing the paroxysms and the resulting pain or cardiac asthma. The condition should be differentiated from angina of effort and coronary thrombosis. Embolism fever and leukocytosis may sometimes occur with or follow paroxysmal arrhythmias, a consideration which must be reckoned with in the study of patients with pain suggestive of coronary thrombosis. The cardiovascular changes that occur during a paroxysmal arrhythmia favor vascular thrombosis and it must be recognized that in the face of coronary artery disease, coronary thrombosis may be induced by a paroxysm of rapid heart action. The prevention or curtailment of such paroxysms by quinidine and other methods offers a prophylactic measure against coronary thrombosis in a small number of patients.

Coronary Thrombosis and Angina Pectoris—Sproull reports two cases of angina pectoris induced by paroxysmal tachycardia which resembled cases of coronary thrombosis. Because of the difficulties of establishing the diagnosis of paroxysmal tachycardia as a cause of angina pectoris it clearly appears that the proper and safe procedure is to treat suspected cases as if coronary thrombosis were present, mindful however, of the necessity of reserving ultimate diagnosis until all possible evidence has been accumulated and considered and expert consultation and advice have been obtained. Because of the similarity of the two conditions and because of the variation in their prognosis and treatment a complacent acceptance of the diagnosis of coronary thrombosis in attacks of severe angina pectoris with tachycardia is to be avoided.

The Schwartzman Phenomenon—Pabst and Branham state that serum neutralization of the Schwartzman phenomenon produced by filtered meningococcus washings is not restricted to antimeningococcus serums but occurs also with antipneumococcus, antidyenteric and antigonococcus serums and with diphtheria antitoxin as well as with normal horse and rabbit serums. This nonspecific neutralization is so frequent and so marked that it seems to limit the usefulness of the Schwartzman phenomenon in the evaluation of therapeutic antimeningococcus serums.

Treatment for Delayed Union in the Tibia—For delayed union in fractures of the tibia Faulkner applies a light snugly fitting unpadded plaster cast from the toes to the level of the upper end of the tibia, or, if the upper third of the leg is fractured the plaster extends above the knee. No padding is used except a little about the heel and the malleoli. The plaster bandages are applied directly to the skin. The direct application to the skin not only makes a snug fit but also gives additional fixation as the hairs are actually incorporated in the plaster. The cast is modeled closely about the malleoli and especially well about the tuberosities of the tibia. When the plaster has set slightly, the walking iron is applied. This consists of a malleable iron bar bent into the form of a flat bottomed U, long enough to reach from about 1 1/4 inches below the plaster sole to just below the tuberosities of the tibia with a horizontal bar at each end the length of which is roughly one fourth the circumference of the upper portion of the cast. This iron is shaped to fit snugly against the plaster cast in the long axis of the leg being offset slightly at the ankle, and is then incorporated in the cast with one or two more plaster bandages. As soon as the plaster is hard weight bearing is encouraged preferably with a cane only. The method is used as a routine in the treatment of fractures of the tibia in Bohler's clinic in Vienna.

Vitamin D Milk—McBeath and McMahon furnished 1 quart of vitamin D milk to twenty-five mothers who were selected from a prenatal clinic at about the sixth month of pregnancy. At 2 months of age and each month thereafter the baby was to be returned to the pediatric clinic for thorough physical and roentgen examination. Control babies were selected from the pediatric clinic at 2 months of age and given the same examination once a month. The diets of the mothers in the two groups varied only in the vitamin D milk, the control mothers having a quart of ordinary milk daily. The study was to be continued until the babies were 6 months old. A definite protection against rickets was evident in the infants of the mothers who used vitamin D milk during pregnancy and lactation and as a complementary feeding. The severity and overwhelming incidence of rickets in the control cases compared to a milder type and fewer cases in the vitamin D group, can be interpreted in no other way.

Scarlet Fever Followed by Meningeal Hemorrhage Case E W Goodall —p 117

Rubella Complicated by Purpura Haemorrhagica—Gunn reports the case of a girl aged 9½ years who gave a past history of measles whooping cough and chickenpox and a liability to mild attacks of epistaxis from the age of 5 years. Two days prior to admission the patient had a headache, followed the next day by a sore throat and the appearance of a rash on the face and chest. The rash was general and macular, with some of the lesions irregular and blotchy. The next day the rash was still manifest but the macules were receding from the face and trunk, while still marked on all four extremities. In the afternoon a dozen or so minute (pinhead or less) petechiae appeared in each supraclavicular fossa and four or five similar lesions were seen closely grouped together in the antecubital fossae. At midnight a severe attack of epistaxis from the right nostril took place suddenly. The next day more petechiae appeared above both clavicles. Oozing continued from the right nostril. An injection of 40 cc of horse serum was given intramuscularly with no benefit. On the following day the epistaxis had considerably diminished but more petechiae appeared over the upper end of the sternum and on the flexor surfaces of both forearms and thighs. A large discolored swelling appeared at the site of the serum injection. An intramuscular injection of 20 cc of a preparation of thrombogen and antithrombin was given, followed a few hours later by 50 cc of the mother's whole blood. Transfusion was not feasible as the patient's serum agglutinated the mother's cells in less than two minutes. Profuse hemorrhage appeared the next day from the left nostril while a slight oozing continued from the right nostril. This was accompanied by moderate fever considerable malaise and pallor of the mucous membranes. Next day the bleeding ceased but melena was present probably from swallowed blood. The general state was decidedly better the temperature fell to normal, and an uneventful recovery ensued apart from the occurrence of serum disease characterized by pyrexia for three days malaise, and a profuse urticarial and morbilliform rash. Of the three blood examinations performed no abnormal red or white cells were noted but slight polychromasia of the red corpuscles was present on the second examination. The Wassermann reaction in the blood serum was negative.

Ephedrine Dermatoses—The comparison of Abramowitz and Noun of the reports of cutaneous symptoms produced by ephedrine and ephedrine showed few such reactions from ephedrine. Since the introduction of ephedrine an increasing number of skin reactions have occurred particularly from the natural product. The synthetic preparation ephedrine is reported to have given a negative reaction in two cases tested. The authors cite nine definite reports from various authors on ephedrine dermatitis and an additional one occurring in their practice. These do not represent the total number of cases. The types of eruption that occurred were eczematous dermatitis and those usually grouped among the erythemas (eczematous urticarial scarlatiniform erysipeloid and purpuric lesions

followed by desquamation). Both the eczematous and erythematous types of lesions were usually present in the same patient, the eczematous eruption predominating. The invariable situation of eruptions on the nose and lips even though present on the other parts of the body, pointed to local absorption followed by general dissemination through the circulation. Various types of lesions occurred, irrespective of whether the drug was used locally or given by mouth. Therefore the eruptions were dependent more on the amount absorbed and the individual state of susceptibility than on the method of administration. Sensitization usually developed soon after the use of the drug was started, but in one case it did not occur until it had been employed for two years. The patch or contact test was of great aid in determining the specific sensitizing agent and establishing the cause of the eruption. It was positive in those with eczematous lesions. The scratch test was mostly positive in those with lesions of the erythema group. The authors obtained a positive Prausnitz-Küstner reaction (passive transfer) but were unable to perform further tests to confirm it.

Treatment of Psoriasis—Wrong treated ten patients, who were suffering from psoriasis by the injection of scales. His technique was essentially that of Tomr. The chief modification was that the scales were weighed and 1 cc of sterile physiologic solution of sodium chloride was added to each 10 mg of scales. Five of the ten patients were definitely improved one of them being entirely cleared, one was slightly improved and four showed no improvement, one receiving more intensive treatment than any other.

Cure of Malaria—Hoopes states that the points in favor of the use of an amino acid derivative (atebrin) in place of quinine are as follows: 1 The fever is usually reduced as quickly as with quinine it is uncommon to find a temperature above 99 F after forty eight hours of treatment. 2 With the exception of subtertian gametocytes it is rare to find malarial parasites in the blood after the second day of treatment. 3 The treatment consists in the administration of 1½ grains (0.1 Gm) of the drug three times a day for five days only as against a prolonged course of quinine. 4 The drug is not unpleasant to take and is not depressing. It is well tolerated even by pregnant women and young children and in bile-water fever and also by persons suffering as well from other diseases such as pneumonia and influenza. 5 Relapses are rare. 6 The cost of a course of this drug is less than that of quinine. 7 In malaria of the benign tertian and quartan type only this drug is necessary. 8 In subtertian malaria it is necessary to give a five day course of plasmochin in addition to the amino acid derivative. 9 This derivative is a powerful preventive of malaria in the sense that no patient treated with it became cured are rid of the malarial complex completely active to Anopheles.

Acetylcholine in Treatment of Epilepsy—McLaughlin investigated the therapeutic effect of acetylcholine and a choline derivative in fourteen epileptic patients. They were subject to frequent major convulsive attacks, which were unassociated with an ascertainable organic disorder in the nervous system or elsewhere. During the experiment no change was made in the diet, usual medication or regimen of the subjects. The type and frequency of all convulsions, auras and equivalents were recorded for stated periods before, during and after treatment. No beneficial effect was observed during the administration of the choline derivative. During acetylcholine treatment there was a reduction of the number of seizures in five patients. There was no association between the decrease in the number of convulsions and the increased dosage (0.3 Gm, the initial dose being 0.1 Gm followed by a daily dose of 0.15 Gm) given during the second week. In two patients, diminution in the number of seizures was accompanied by an increase in psychic equivalents. No change in the type or severity of the seizures was observed in the other three. One patient became brighter and more energetic, and thus mental improvement was maintained for some weeks, although the number of fits again increased after treatment. There was no mental change noted in the two patients, who showed decrease of fits during the injections. One patient in whom a decrease in the number of seizures occurred during the fourteen day period succeeding acetylcholine administration, was confined to bed at this time. In another a great increase in the number and severity of attacks coincided with the end of the choline derivative treatment. An attempt to arrest the rapidly repeated seizures by two 0.4 Gm doses of acetylcholine failed, and this form of treatment was in consequence stopped.

*Enterogenous Cyst Record of Case A C Forrester—p 202

Enterogenous Cyst—Forrester reports a case of enterogenous cyst in a boy, aged 5, and states that, clinically two types may be differentiated. The first is that associated with acute complications and constitutes about 50 per cent of all cases; the case reported by the author is of this type. In most instances there is acute intestinal obstruction due to volvulus and, unless immediate surgical intervention is carried out, the outcome is fatal. The second type is characterized by a diversity of symptoms and signs. Many cases give a history of mild recurrent attacks of partial intestinal obstruction, dragging pain or some abdominal fullness is commonly present, in others, definite signs may be found, such as a freely movable tumor, which has a wide range of movement, but such cases are rare. The treatment for the acute case is the immediate relief of the obstruction, the magnitude of the operation depending on the patient's condition. With regard to the second type, drainage has been tried in those cases in which the communication between the lumen of the cyst and that of the intestine has been occluded, but the end-results are poor in that fistulas may result, and hence enucleation is a better form of treatment. In the cases in which the intestine is involved—and these constitute the majority of this type—resection of the intestine must be undertaken.

Heart, London

After Histories for Ten Years of a Thousand Men Suffering from Heart Disease Study in Prognosis R T Grant—p 275

Coarctation of Aorta—Lewis records nine cases of coarctation of the aorta of the adult type, including three necropsies. High blood pressure was a feature in all cases and has been observed to continue over periods as long as thirteen and one-half, fifteen and sixteen and one-half years. From observations

in such cases it is manifest that high blood pressure does not lead to progressive enlargement of the heart. The electrocardiograms usually present the signs of left-sided preponderance. The author concludes that prolonged overwork does not in itself cause heart failure. In coarctation, the average lag of the femoral behind the radial upstroke is but 0.032 second. The delay appreciable by palpation is due to delay in the summit of the femoral pulse, this lag averages 0.145 second. Measurements of the flow of the blood to the leg give normal values. In the head, neck and hand, vasodilatation seems to be the rule. It has not been established anatomically that in coarctation there is a mechanical obstruction to the outflow of the blood from the heart, at the first branching, constriction of the isthmus is compensated for by dilatation of the branches of the aortic arch. If coarctation is to be diagnosed with reasonable frequency, the femoral arteries must be felt in all cases of continuous high blood pressure, to ascertain whether the pulse is small and whether its summit lags behind the radial summit.

Acetylcholine in Man—Carmichael and Fraser observed that intravenous doses of from 0.01 to 0.03 Gm of acetylcholine are necessary to produce cardio-inhibitory effects, which appear from five to ten seconds after the injection and last for a few seconds only. The slowing of the heart is followed by a rise of rate above the original level with a return to normal usually in a half to one minute after the injection. The systolic and diastolic blood pressures fall during the phase of slow heart rate but return to the original level or a little higher during the phase of rapid heart rate. The phase of rapid heart rate is accompanied by flushing of the face, neck and upper thorax, and a feeling of warmth throughout the body. Occasionally there is slight flushing of the limbs. Coughing and a sensation of obstruction to respiration frequently accompany the phase of slow heart action. The nature and intensity of the response vary in different persons. The response can be abolished by the previous injection of atropine, but not by the previous injection of epinephrine. The previous injection of physostigmine intensifies and slightly prolongs the response. Intrarterial injections produce flushing of the skin twenty seconds later in the corresponding territory. Acetylcholine given by subcutaneous and intramuscular injection in doses up to 0.5 Gm has no appreciable effect.

Treatment of Amebiasis—Chopra and the Sens gave 4-carbamino phenylarsonic acid to thirty-one patients suffering from chronic intestinal amebiasis; twenty-three were cured, the drug failed in four and the result was indeterminate in four. The criterion of cure was based on five or more negative examinations of the stools on different days after the cessation of all treatment. This compound has amebicidal properties and is given in doses of 0.25 Gm in gelatin capsules twice daily. The proportion of probable cures to failures in this series was 57.5% as compared with 35.1% obtained by Knowles in a similar series with emetine bismuth iodide and 31.6% obtained by Acton and Chopra with kurchi bismuthous iodide. The drug produced no untoward effects in the doses administered.

*Protein Shock Therapy in Undulant Fever S Miller—p 1177

Chronic Ulcer of the Leg—Cokkinis states that chronic indolent ulcer of the leg is one of the results of prolonged venous and tissue engorgement, usually caused by varicose veins. It has a sharply localized distribution and is frequently a painful and disabling condition. It can be healed only by measures that correct the loss of vascular balance, and even then it is apt to recur. The ambulatory treatment consists of compression by elastic bandages and the obliteration of the varicose veins by injection and possibly ligation. It produces healing of the original ulcer in 80 per cent of cases and improves some of the remainder. The disadvantages of the elastic bandage treatment are that (1) it fails to heal a fifth of the ulcers, (2) recurrence is likely to occur at some future period in from 25 to 50 per cent of the cases, (3) it tends to aggravate eczema. The last disadvantage can be counteracted by the use of protective preparations under the elastic bandage. The first two disadvantages are not peculiar to ambulatory treatment. The advantages of the ambulatory method overshadow its disadvantages. It is relatively inexpensive, gives early relief, heartens the patient by producing rapid diminution of the ulcer and usually saves the patient much waste of time and money. Skin grafting does not benefit more than a small proportion of indolent ulcers. Prolonged after-care is most important and recurrences must be treated early.

Protein Shock Therapy in Undulant Fever—In treating a series of patients suffering from undulant fever Miller has consistently used protein shock therapy giving a TAB injection intravenously and repeating it every three to five days. He presents the case histories of the seven patients who received from one to five TAB injections. The result of treatment has been uniformly good, while in three of the patients its effect was dramatic and the illness was brought to an abrupt termination by only one injection. There have been no recurrences.

Treatment of Auricular Fibrillation and Flutter T F Cotton—p 698
Elements of Electrocardiography C Wilson—p 705

Rheumatic Heart Disease—Miller states that the prevention of rheumatic heart disease is bound up with the prevention of rheumatism. Heart disease is not the first of the rheumatic manifestations; it tends to accompany the later and more severe forms of the infection. The graver forms of rheumatism with their added danger to the heart are preceded by weeks or months during which minor and perhaps doubtful symptoms are present. It is during this stage of invasion that there is the best chance of preventing heart disease. The early recognition of the rheumatic tendency is the most important measure in preventing heart disease. When the presence of rheumatism is recognized or strongly suspected the routine procedure for the prevention of heart disease may consist of the following: 1. Regular

reevaluations of the child should be made, as only a proper examination of the heart can detect the early signs of its involvement. 2. The general environment of the child should be borne in mind and every effort should be made to provide the patient with proper clothing, dry rooms and wholesome food. 3. Exacerbations of rheumatic symptoms must be strictly treated. The recurrence of pains should be reported to the physician and, should they be accompanied by any rise in temperature, rest in bed should be ordered. 4. The removal of infected tonsils is indicated in this disease. 5. Salicylates should be given regularly in small doses over long periods. For this purpose the most suitable is acetylsalicylic acid in doses of from 5 to 10 grains (0.32 to 0.65 Gm.) night and morning.

Coronary Thrombosis—Bedford believes that in coronary thrombosis at the onset morphine is urgently required and should never be withheld, even when there is vomiting. The dosage must be adequate to afford relief from pain, and from one-half to one-fourth grain (0.03 to 0.016 Gm.) should be given at the start and a second dose if necessary. The bowels may be disregarded for the first few days when an enema may be given. Warmth is important. Dextrose by mouth and liquid foods are all that is required at first. Digitalis is required only if heart failure occurs or if there is auricular fibrillation, and moderate doses, such as 20 minims (1.2 cc.) three times a day, should be used. In cases of ventricular tachycardia quinidine can be tried provided electrocardiographic proof of the abnormal rhythm has been obtained. From 5 to 10 grains (0.32 to 0.65 Gm.) may be given and repeated in two hours in urgent cases. The most important part of the treatment is an adequate period of complete rest in bed. Convalescence should be gradual. When the infarct has healed and in the absence of anginal pain and of dyspnea, reasonable activity is to be encouraged rather than restricted.

Auricular Fibrillation—Cotton points out that the main object of treatment in auricular fibrillation is to make the patient comfortable until the normal rhythm is restored. A chloral hydrate mixture in 10 gram (0.65 Gm.) doses, repeated three or four times at four or six hour intervals is useful for this purpose. Chloralamide in cachets of 10 grains, repeated in the same way, is equally effective in calming the patient. Firm pressure on the carotid sinus over the carotid artery below the angle of the jaw for ten or fifteen seconds may release a mechanism, through the vagus nerve which can terminate the attack. If vomiting is induced the paroxysm may be shortened. Quinidine sulphate 3 grains (0.2 Gm.), given every four hours, has a specific effect in controlling this disturbance of rhythm. Digitalis should be withheld as it may establish a chronic state of fibrillation. A prolonged rest is not required after the normal rhythm has returned, unless symptoms of heart failure have developed during the attack. Quinidine may be prescribed between the attacks for its effect in lengthening the intervals and shortening the duration, the dose is 3 grains three times a day and if necessary, it can be increased to 15 grains (1 Gm.) in the twenty-four hours, the extra 6 grains (0.4 Gm.) to be taken at bedtime. When auricular fibrillation has lasted for more than ten days, it will not revert to a normal rhythm spontaneously. Treatment should relieve the heart of the heavy task which the rapid ventricular rate produced by the fibrillation has imposed on the ventricles. This can be obtained by giving digitalis in doses large enough for the drug to accumulate in the tissues of the body. A daily dosage of 1 drachm (4 cc.) of the tincture for five days or a week is indicated when the ventricular rate may be expected to fall to 70 or 80, at this level the dose should be halved and continued as long as the rate does not fall below 60. Profound slowing with coupling, nausea, vomiting and diarrhea are indications for withdrawal of the drug and complete rest. When these toxic effects have disappeared digitalis control can be resumed in the amount required. Gastric symptoms may be avoided by prescribing the drug well diluted and after food. The patient should always be kept at rest when digitalis is given in large doses during the initial stages of the treatment. In auricular flutter the slowing of the ventricular rate can be accomplished by giving digitalis in sufficiently large doses to produce the required slowing of the ventricles and by continuing the use of this drug in doses that will maintain a slow ventricular rate. In restoring the normal rhythm, the dosage and the management of the case is that of auricular fibrillation.

Annales de Medecine, Paris

Lipases of Serum N Fiessinger, M Albeaux Fernet and A Gydos —p 101

*Hepatic Organotherapy Parenteral Administration of Large Doses M Villaret L Justin Besançon and Mme and H Desoille —p 136
Phonocardiography C Ivan and M Racine —p 157
Electrocardiographic Studies Monopolar Curves R Lutembacher —p 175

Various Effects of Liver Extract—From an experience of many years Villaret and his associates state that liver extract is infinitely more active when administered by the parenteral route (subcutaneous, intramuscular or sometimes intravenous) than by mouth. The quality of the extract and the dose injected are important. They employ the hepatic extract in two concentrations from which the protein, albumin and lipoids have been extracted, and the more concentrated one is also almost completely deprived of histamine and choline. Of the weak extract, 1 cc equals 0.1 Gm of dried extract or 0.3 Gm of fresh liver, of the strong extract, 2 cc corresponds to 10 Gm of the dry extract or 30 Gm of fresh liver. The indications for parenteral liver extract are extensive. In small doses, it prevents or diminishes the accidents of toxic medications such as arsenic, mercury, bismuth, iodine, vaccines and serums, and increases their efficacy. For this purpose, 1 cc. of the weak extract may be given with each injection. In medium quantities (from 1 to 10 cc of the weak extract in daily injections), it undeniably improves certain symptoms of slight hepatic insufficiency, migraine, urticaria, pruritus, eczema, erythrodermia and acne. In infections, intoxications or cirrhotoses, accompanied by more or less pronounced hepatic insufficiency, the latter is considerably reduced by the use of liver extract. The dosage may vary from 10 to 30 cc of the weak extract, depending on the case. In grave icterus, injections of the strongly concentrated liver extract in doses of from 2 to 4 cc (corresponding to from 30 to 60 Gm of fresh liver), and even higher, effectively combat the hemorrhages and nervous phenomena and noticeably retard the fatal evolution of the disease. In a case of cirrhotic hepatic insufficiency accompanied by erysipelas, it arrested a beginning grave icterus. In rare patients, too strong doses seem to provoke hepatalgia and diarrhea or reawaken former biliary colic.

Mechanism of Cardiovascular Tonus D Danielopolu —p 1297
*Critical Study of Vitamins B R Lecoq —p 1300

Study of Vitamins B—On the basis of his own experiments and of the publications made to date on the complex questions of the vitamins B, Lecoq feels justified in affirming the existence of three distinct vitamins B. Vitamin B₁, the antineuritic vitamin which controls the nervous equilibrium, is labile to heat and alkalis. It is also designated vitamin B-P or F. Vitamin B₂ is antidermatitic and is above all the vitamin of cellular life and growth. It is stable in the presence of heat and alkalis. It corresponds to vitamin D of Funk and Dubin, and to vitamins G and P-P. Vitamin B₃, the antidenutrition vitamin, is indispensable to the utilization of glucides, proteins and lipoids. It is relatively thermostable but is labile in the presence of alkalis. It is identifiable with vitamins B₄ and B₅ and has sometimes been designated by the letter H.

Treatment of Gastric and Duodenal Ulcers R Leriche —p 1313
*Unrecognized Therapeutic Use of Sodium Thiosulphate J Kabelik —p 1315

Unrecognized Therapeutic Use of Sodium Thiosulphate—Kabelik states that sodium thiosulphate deserves to be used much more extensively than it is at present and calls attention to some of its indications. Relying on the hypothesis that its therapeutic action consists chiefly in protecting the colloidal condition of the serum he has used it with favorable results in many diseases. In intravenous injections it acts as a stimulant of the reticulo-endothelial system; it modifies the reactions of the organism in severe burns and in eclampsia, especially the preeclamptic states and it favors chemotherapy in septicemia. It has a remarkable action in certain neuralgias and in rheumatism. It acts as an antidote in intoxications

with tincture of iodine or potassium permanganate, if used in gastric lavage. Used intravenously it is an antidote for intoxication with compound solution of cresol, arsenic and heavy metals. The complex salts of thiosulphate and the heavy metals have a selective affinity for cancerous tissues. It sensitizes them to actinotherapy and should therefore be associated with the latter. In addition to sodium thiosulphate the author employs the thiosulphate of magnesium, of calcium of copper and lead, and also its selenium salt associated with sodium thiosulphate in a relatively constant and stable solution. In these solutions there is always an excess of sodium thiosulphate, sometimes of dextrose. Usually 2 Gm of thiosulphate and 2 Gm of dextrose are injected intravenously.

*Erythrocyte Sedimentation Speed in Surgical Diseases of Biliary Tract G Picardi —p 1369
*Treatment of Anemia of Pernicious Type with Intravenous Injection of Epinephrine U Diliberto —p 1372
Echinococcus Cysts of Neck Case D Curri —p 1373

Sedimentation Speed in Diseases of Biliary Tract—Picardi studied twenty patients with calculous cholecystitis and icterus and ten with various surgical diseases primarily duodenal ulcer. The venous blood was taken on a fasting stomach the day before and after operation and to it was added an anticoagulating solution. Readings were made every fifteen minutes for the first hour every hour for the next five hours and after twenty-four hours. In some patients the examination was repeated together with the test of coagulation and bleeding time. The author found that whereas the sedimentation speed increases after operation and gradually diminishes until the normal rate is attained in from two to fourteen days, there is a diminution in the coagulation time perhaps in relation to the platelet crisis following surgical intervention. In some patients with lesions of the biliary tract there was a diminution of the sedimentation speed while others showed a slight increase. In these patients there was always jaundice, in which urobilin-icterus predominated. Many patients had cholelithiasis of long duration others, reactivations of calculous cholecystitis. The author concludes that the sedimentation speed test is not constant in diseases of the biliary tract and is of slight value in similar diseases.

Anemia of Pernicious Type Treated with Epinephrine—Diliberto treated a patient with grave anemia, lacking Hunter's tongue and leukopenia to be completely pernicious in type. After the number of erythrocytes was determined at 1,600,000, the patient received an initial dose of 0.01 mg of epinephrine and, following that, daily injections of one ninetieth, one eightieth and so on to 0.1 mg. The last dose was repeated for twenty days, so that in thirty days the cumulative dose was 23 mg. After that, the spleen had returned to its physiologic limits. The red globules returned to normal as well as the hemoglobin and reticulocytes. The leukocytes remained invariable and the platelets oscillated around 250,000. After treatment, the hematologic picture showed no change and the patient remained in good health. Examination of the gastric content following injection of histamine showed the patient to be achylic.

Importance of Chronaxia in Cardiology—Castex and Lopez Ramirez say that chronaxia has a clinical and therapeutic value in the physiology and pathology of the heart. They consider the heart a neuromuscular entity constituted of three different systems: striated muscle tissues, a network of specific conductive tissues and an extrinsic vagosympathetic nervous

system These three systems are in intimate anatomic and functional relation to each other and to the intracardiac blood supply system The chronaxic value of each of these systems is different from the other The harmonious functioning of the heart depends on the maintenance of the heterochronic proportional relations of the systems The alteration of the chronaxic value of any of them causes a functional disequilibrium, which affects the excitability of the heart The chronaxia of the heart is the numerical exponent of the excitability of its tissues All causes that modify the tissular excitability have a repercussion on the chronaxic values, which, when reaching certain abnormal limits, are a sign of organic disturbance, which has the same diagnostic importance as the deformations of the electrocardiogram The authors review the literature on the relation of chronaxia with the disturbances of auriculoventricular conduction and with the changes of the QRS phase of the ventricular electrocardiogram They state that the changes of the ventricular electrocardiogram are caused by disturbances of the chronaxia, which represent the repercussion of either organic or functional disturbances of Tawara's node, of the bundle of His or of its branches The current of cardiac action is a function of chronaxia and, if it is proved that its ascending phase has a duration of three or more chronaxic values (as Lapicque states), it is admissible to speak of a precise and practical numerical relationship between the two functions of the myocardium, that is, between its excitability and its conduction The chronaxia has a clinical value in the physiology of the heart because the electrocardiogram can be interpreted by establishing a relation between its various phases and the chronaxic value of the different segments and tissues of the heart The tissular lesions of the cardiovascular system can be localized by the interpretation of the electrocardiographic changes, in accordance with the chronaxic value of the pathologic segment The chronaxia is also of therapeutic value because several drugs (especially certain alkaloids), as well as certain toxins and poisons have an action of selective fixation on certain groups of muscles which action is regulated by the chronaxic value of their receptive nervous elements and can serve as a basis to regulate the administration of those drugs

Bone Endothelioma and Bone Tumors—Petrov and Glasunow describe a tumor of the shaft of the tibia which on histologic examination presented the characteristics of a basilioma Seven similar cases of primary epithelial bone tumors culled from the literature are described The localization of the tumor was seven times in the tibia and once in the ulna This occurrence in a long bone close to the skin suggests the possibility of ectodermic implantation Five out of the eight were basal cell tumors without cornification and three were basal cell tumors with parakeratotic cornification In contradistinction to carcinomas secondary to a tumor of the kidneys, the lungs or the prostate in which the parent tumor is often not recognized the basal cell carcinomas limited to the skin and readily inspected mucous membranes could not be long overlooked All the eight instances reviewed were apparently primary epithelial bone tumors of embryonal origin, and not metastases Because of the scarcity of observations no definite clinical picture can be evolved A correct diagnosis before

the histologic examination was not made in a single instance The diagnosis was usually that of a sarcoma, myxoma, chondroma, giant cell tumor or a bone cyst Metastases were not observed The tumor is apparently not very malignant, though the possibility of invasion and of metastases cannot be definitely excluded The proper treatment consists of resection of the involved portion of the shaft of the bone and its osteoplastic replacement by a bone transplant The authors state that, excepting hemangiomas, there are no proved cases of bone endotheliomas On the other hand they feel that on the basis of the eight cases described, the primary epithelial bone tumors should be included in the classification of bone tumors

Pancreatic Juice in Bile Ducts—Popper examined the bile, obtained at operation from 219 patients, for the presence of pancreatic ferments Of these, 161 were from patients with cholelithiasis eighteen from patients with pancreatitis, six from patients with neoplasm of the gallbladder and one from an instance of bile peritonitis without a visible perforation of the gallbladder Pancreatic ferments were demonstrated to be present in the bile of 17 per cent of the patients investigated The finding of normal gallbladders and normal bile ducts in several instances in which the pancreatic ferments were present in the bile suggests that the occurrence alone is not necessarily abnormal and need not lead to pathologic changes Regurgitation of the pancreatic juice into the common bile duct acquires a pathologic significance only when combined with stasis resulting from obstruction to the return of the secretion A stone in the choledochus or in the papilla of Vater is the most frequent cause of such an accident Obstruction to return of the pancreatic secretion will then lead either to a bile peritonitis without visible perforation of the gallbladder or to an acute pancreatitis In the sixteen cases of acute pancreatitis the author found the pancreatic ferments in the bile ducts in every instance He believes that the entry of the pancreatic secretion into the choledochus combined with stasis, causes activation of the trypsin in the mixture It is conceivable that the activation occurs in the lower pancreatic portion of the common bile duct and that the process spreads by diffusion and involves the pancreas The reverse, namely, the entrance of bile into the pancreatic duct, was demonstrated only exceptionally in postmortems on patients dying of acute pancreatitis The author does not feel that pancreatic necrosis and acute pancreatitis are distinct entities His results suggest that they represent the same process in different states, the difference in the intensity of the pathologic picture depending on the stage of digestion during which the pathologic activation of the trypsin takes place

Reticulo-Endothelial System and Ovarian Function—Uebermuth states that in the past the functional activity of the reticulo endothelial system in women has been determined by the application of the so-called endothelium test, which consists in raising the pressure within the capillaries by the application of a constricting band The appearance of petechial points below the constriction is indicative of vulnerability of the capillary wall and constitutes a positive test Another way of testing the functional capacity of the reticulo endothelial system is by testing its resorptive power To this purpose the author uses the congo red test as developed by Adler and Remann Twenty cubic centimeters of blood is removed from a vein of the arm of a fasting person and this is followed by the injection of 12 cc of a 1 per cent watery solution of congo red Four minutes later and sixty minutes later, 5 cc specimens are drawn from a vein and the scrums separated out The scrums are tested spectroscopically, and those containing

admixture of hemoglobin are discarded. The congo red index of the tested specimen is arrived at by comparison with a standard solution of congo red. The test in women with a normal sexual cycle has established that the normal index amounts to from 40 to 70. The test depends on the well known fact that congo red, when injected into the circulation, is first deposited and later excreted mainly by the Kupffer cells of the liver, and only to a negligible extent by the kidneys. The congo red content of the blood, four minutes and sixty minutes after its introduction into the blood, serves as a fairly accurate index of the functional capacity of the reticulo-endothelial system. The object of this study was to determine the influence, if any, of the ovarian hormones on the functional capacity of the reticulo-endothelial system. The author found that this function was lowered in women with diminished or lost sexual function, namely, in patients presenting climacteric, menopausal and pathologic states with ovarian dysfunction or amenorrhea, or in patients surgically or roentgenologically castrated. These observations suggest that the function of the reticulo-endothelial system is subject to regulating influences of the sex hormones. Benda's observations that the absorbing power of the reticulo-endothelial system is lowered in the second half of pregnancy, probably owing to the loss of the protective function of the corpus luteum, is in agreement with the author's results.

Insulin in Nondiabetic Disturbances During Childhood—In his study on the use of insulin in nondiabetic disturbances during childhood, Rau cites observations indicating that insulin increases the receptivity of the tissues for nutritional substances in general, accelerates the digestion and increases the entire metabolism. He describes experiments showing that disturbances in the water exchange, infections and metabolic disturbances impair the normal insulin mechanism in nondiabetic organisms. In discussing the possibility of the therapeutic use of insulin, he points out that the process of growth taxes all organs to capacity and that young tissues have a particularly great need of carbohydrates. Experiences with insulin therapy of nondiabetic children are reported. The children generally received two injections each day, at 6:30 a. m. and 6:30 p. m. The daily dose differed according to the weight of the child, that is, from 1 to 3 units was given for each kilogram of body weight. The deep subcutaneous injections were made in the thigh or in the buttock. The insulin therapy was instituted only in children in whom other therapeutic methods had failed, and, when the insulin injections were begun, the quantity and type of food were continued as before. The author first relates his observations on twenty-four nurslings and states that in twenty-one the insulin produced favorable results in one the effect was not convincing and in two the treatment failed entirely. However in one of the latter two there was severe atrophy and the nursling was already in such poor condition that recovery was impossible. The other failure was a case of microcephaly and apparently inferior constitution. The author employed insulin therapy also in five children with intestinal infantilism. Dietetic measures alone

had failed and the children suffered from severe hydrolability. The insulin therapy, of course, did not effect a permanent cure of the intestinal infantilism, but it made it possible to overcome periods of digestive insufficiency which endangered life and to stimulate the impaired metabolism. Of eight children with chronic undernutrition, due either to insufficient diet or to constitutional factors, five responded favorably to insulin therapy, and, of twenty-two children with secondary dystrophy, only three failed to respond favorably to insulin therapy.

A New Disease Entity Among Hepatosplenomegalias

—Among the rare hepatosplenomegalias with reticulo-endothelial hyperplasia occurring during childhood, Siwe combines into one group several cases that have the following characteristics: considerable enlargement of the spleen, moderate or great enlargement of the liver, moderate or pronounced swelling of the lymph nodes, a severe hemorrhagic tendency, particularly in the form of purpura, and a mild secondary anemia without characteristic leukocytosis or leukopenia and without monocytosis. The number of thrombocytes is normal or increased. The onset of the disturbance is acute and feverish, either with or without a demonstrable banal infection. The course is rapid and, under constant exacerbations, death finally follows within several weeks or months. The blood cultures remain negative. The splenic punctate reveals considerable reticulo-endothelial hyperplasia, eventually with admixture of leukocytes but without eosinophilia and without the typical deposits that characterize the cells in Gaucher's disease or in Niemann-Pick's disease. The author states that nothing definite can be said as yet about the etiology. He considers an infectious cause most likely, but whether this is the direct cause of the hyperplasia or whether it leads to it indirectly by way of a metabolic disturbance is not yet known. It is also possible that a primary metabolic disturbance may cause the changes but the functions and reactions of the reticulo-endothelial system are not yet sufficiently understood to determine the cause and the number of reported cases is too small to permit reliable knowledge about the pathogenic course.

Cancer Prophylaxis and Predisposition to Cancer

—After reviewing earlier studies, which proved to him that there is a possibility of specific antibody formation in animals with cancer and that the anticarcinoma substances are formed primarily in the spleen, Braunstein reports experimental and clinical studies with an extract prepared from the spleen and the reticulo-endothelial system of animals treated with tumor material or with blood from tumor patients. To these organ extracts, certain electrolytes were added. He found that the oral administration of the preparation to animals altered the predisposition to cancer, so that a large percentage of the animals became immune to it. This immunity persisted for months after cessation of the treatment. In animals in which inoculation tumors had taken root there was an inhibition of the growth amounting to 80 per cent. It was also observed that the animals treated with the preparation outlived the control animals by several months. Tumors that grew in relatively immune animals did not grow when further transmitted. When pregnant rats with tumors were treated with the extract the tumors that had retrogressed during pregnancy did not grow again after the animals had littered contrary to what

occurs in the tumor rats that have not been treated with the extract. The immunity that has been produced by the extract is hereditary in animals. Blood tests on animals as well as on human beings revealed that the preparation produces a defense reaction in the form of a monocytosis. The action of the preparation was corroborated also in Carrel's tissue cultures, in that the blood serum of rats immunized with the preparation inhibited the growth of the tumor cells. Investigations conducted according to Warburg revealed in some experiments an increase in the respiration intensity of the erythrocytes of rats and rabbits treated with the extract. Although no direct proof, this is, in view of the similarity between carcinoma tissues and the anuclear erythrocytes an indirect proof of a change in the energy metabolism (increase in oxidation and decrease in glycolysis). The author thinks that precaution is still advisable in drawing practical conclusions. However, he thinks that the identical defense reaction produced with the preparation in the animal and in the human organism, as well as in the healthy and in the cancerous organism, and the possibility of spontaneous cures of cancers in animals and in human subjects, justifies the consideration of an "internal" cancer prophylaxis. He considers the use of the preparation indicated under the following conditions: in suspected carcinoma, after ventricular or duodenal ulcers in precancerous conditions, in case of benign tumor after operative removal of tumors, during and after irradiation therapy, and in older persons with a heredity of cancer.

Active Colloid of Thyroid in Metastasis of Malignant Goiter—Engelstad reports the case of a woman, aged 82, who for twenty years had had a goiter that remained stationary. Then there developed, without noticeable changes in the goiter, a metastasis in the vault of the cranium. The metastasis had the histologic aspects of a carcinoma of the thyroid. By a biologic method that is, by means of a somewhat modified acetone test, it was possible to demonstrate active thyroid colloid in the metastasis. The quantity of the colloid corresponded to more than 0.25 mg. of sodium thyrone for each gram of substance of the metastasis.

Anesthesia with Highly Volatilized Ether Vapor—Tiegel submits his clinical observations with a new method of ether anesthesia. By means of a newly devised apparatus to be described in a later communication the ether is highly volatilized by being warmed considerably above its boiling point. Anesthesia induced by this method seems to possess characteristics almost entirely different from those of the old drop method of administration of ether. The two interesting features of the new method are that analgesia sets in earlier than the loss of consciousness and continues for some time after the consciousness is regained and that the blood of the patient is highly aerated as evidenced by a rosy color of the face all through the anesthesia and for a few days after. This highly volatilized ether vapor appears to be nonirritating to the bronchial mucosa making its administration possible in instances of bronchitis, colds and coryza. It has a stimulating effect on the circulation. Determinations of the blood pressure during anesthesia oscillated within from 5 to 10 millimeters. The author summarizes the advantages of the method as follows. It is safer than the old method which in itself was considered quite safe for decades. Premedication or combination with other anesthetic agents appears unnecessary. The induction of sleep is pleasant and is not accompanied by excitation. The degree of anesthesia is readily controlled. A stimulating effect

on respiration and circulation is evident. The indication for its use is not limited by age or organic disease. The return of consciousness is rapid. There is an absence of unpleasant postnarcotic phenomena, such as nausea, vomiting, headache and disturbance of the intestinal functions. The apparatus is simple and does not call for great skill in its use. The amount of ether required is less than with the old drop method. The physical and chemical properties of the highly volatilized ether are being investigated at the University of Bonn.

Endometriosis of Bladder—Kohler contributes four observations of endometriosis of the bladder to the twenty-three cases contained in the literature. He thinks the rarity of the observations may be due in part to the fact that the clinical picture of this condition is not well known. Most of the cases reported were not diagnosed until operation. The cyclic changes characterizing endometrioses are particularly apparent in endometriosis of the bladder. In certain locations endometriosis of the bladder may cause little discomfort but, if the endometrioid cysts extend into the mucosa of the bladder, severe pain in the region of the bladder sets in at the beginning or just prior to the menstrual period. During micturition it assumes a convulsive character. It usually extends a few days beyond the close of the menstrual period, lasting from five to fourteen days in all. During the intermenstrual period there are no symptoms. The concurrence of menstrual period and bladder pains, especially if the urine at this period is bloody, is sufficient for diagnosis from the standpoint of anamnesis, as no other disease of the bladder is subject to cyclic changes. Cystoscopic confirmation of the diagnosis is desirable. A slightly projecting tumor on the posterior wall of the bladder, which varies in size from a bean to a nut and exhibits a bluish discoloration due to the endometrioid cysts indicates endometriosis. The cyclic changes are usually visible cystoscopically as increased volume and multiplication of the endometrioid cysts during the menses. The author observed the cyclic changes cystoscopically in three of his cases, and in one case they were obscured by a severe edema surrounding the tumor. Three of the patients had undergone Beutner's operation for adenitis in which the uterine wound is covered with vesical peritoneum. A direct relation between this operation and the endometriosis of the bladder was indicated by the finding in microscopic serial sections of an uninterrupted connection between the proliferating glandular epithelium of the uterine mucosa and the bladder tumor. This is comparable to the conditions found by other investigators in endometriosis of the abdominal scar following laparotomy. Therapy in women nearing the menopause should consist in roentgenologic castration. The disappearance of the cyclic changes causes the disappearance of all bladder symptoms. In younger women, if the tumor is near a ureter, roentgen irradiation is also preferred, in other locations excision of the tumor is advised.

*Clinical Contribution to Acute Lymphatic Leukemia with Mikulicz's Disease. W. Jasinski and J. Szmurlo—p 679

Lymphatic Leukemia with Mikulicz's Disease—Jasinski and Szmurlo report the case of a girl aged 7, which may be an instance of acute lymphatic leukemia with the appearance of organic septicemia. The general course of the illness was one of septicemia. After a period of angina there occurred an infection of the bone marrow. Almost at the same time there arose a bilateral purulent infection of the inner ears.

and a copious eruption. Soon after this appeared the obscure lymphatic leukemia, hemorrhages, leukopenia with relative lymphocytosis, thrombopenia, purpuric spots, necrotic changes in the oral cavity, enlargement of the liver and of the spleen, enlarged salivary glands and soreness over the bones. To this picture was added the syndrome of Mikulicz's disease. In certain instances the condition improves after treatment with neoarsphenamine. The authors state that treatment should be with cinchona, as roentgen rays do not give beneficial results. Erlichowina noticed that roentgen treatment is contraindicated because it produces a decrease in the blood cells. In the authors' patient, treatment with arsenic remained without result, but roentgen treatment evoked worse results.

Various Forms of Flatfoot and Their Treatment P. P. Vreden — p. 208

Bacterial Flora in Development and Perforation of Duodenal Ulcer—Shmejl made a histologic study of fifty stomachs resected for perforating duodenal ulcer. The specimens were fixed immediately on their removal in a 10 per cent solution of formaldehyde. The author studied 1,500 serial sections and found the presence of a bacterial flora at times rather sparse in 94 per cent. Study of other portions of the gastric wall established the presence of bacteria on the surface of the mucosa, resembling in many instances those observed in the area of the ulcer. He did not observe an inflammatory reaction to the bacteria on the part of the tissues, on the other hand, areas with a marked inflammatory process in the absence of bacteria were noted quite frequently. In three resected specimens, no bacteria were found either in the ulcerated area or in other parts of the stomach. A histologic picture of the gastric mucosa in perforating duodenal ulcer prepared after the method of Kalima, showed everywhere inflammatory changes. On the basis of these observations the author rejects the etiologic role of bacteria in the perforation as well as in the formation of ulcers.

Pneumococcal Peritonitis in Children—Ternovskiy reports twenty-six instances of pneumococcal peritonitis in children observed in the Obraztsov Hospital in Moscow. Of these, twenty-one were in girls and five in boys. Fifteen were instances of diffuse peritonitis, and eleven of encapsulated peritonitis. All patients in the first group died while in the group of encapsulated abscesses there was only one death. Diarrhea was noted in 50 per cent. Labial herpes was observed once. Simultaneous involvement of pulmonary tissue was diagnosed in three, although on postmortem it was present in every instance. The author is skeptical about the genital origin of the disease, since he did not observe a single instance of vaginitis in his material. The clinical course of pneumococcal peritonitis is either that of an acute diffuse peritonitis leading to death in from one to seven days or that of a more chronic character in which three fairly definite stages can be recognized. The first stage is that of an acute progressive peritonitis, followed by a stage of subsidence and improvement in general and local symptoms. The second stage is followed by a renewed exacerbation of the abdominal symptoms with later definite signs of encapsulation. On the basis of his own material and that of practically all authors with the exception of Obadalek, the author is opposed to immediate surgical intervention and prefers to wait for signs of definite encapsulation of pus. A simple incision of an encapsulated abscess with or without the use of a drain is usually followed by marked improvement and cure in a high percentage of the cases.

- *Action of Bismuth in Anion Especially with Reference to Preparation Iodibismol J. Strandberg and B. Sjogren — p. 617
*Essential Thrombopenia J. Wahlberg — p. 695

Action of Bismuth in Anion with Reference to Preparation Iodibismol—After Hanzlik, Gurchot, Mehrrens and Johnson's preliminary report on the penetrating power of bismuth in anion and its value in the treatment of syphilis, Strandberg and Sjogren conducted tests with a bismuth preparation with bismuth in anion iodibismol, containing 20.5 per cent of bismuth. They found that the preparation is rapidly absorbed after intramuscular injection, 2 per cent of the bismuth being eliminated during the first twenty-four hours after injection, the maximum elimination occurring about the seventh day, with elimination ended after three weeks. In experiments in animals, about 45 per cent of the injected bismuth was found in the organism, the values in brain and spinal cord corresponding to those in heart and lungs. In 88 per cent of the cases examined bismuth was demonstrated in the spinal fluid. In clinical tests 2 cc of the preparation was injected from every third to fifth day, ten or twelve injections altogether being given. A rapid curative effect was seen both in recent and in gummatous syphilis. The occasional by-effects noted consisted mainly of pain at the site of injection, of varying intensity and always transient.

Essential Thrombopenia—Wahlberg reviews the literature on essential thrombopenia and discusses the case of a hypothyroid woman, aged 20, who presented herself for treatment about one month after the onset of an acute attack of hemorrhagic diathesis believed to be her third. The blood pressure was almost normal, the thrombocyte count about 65,000, and bleeding and coagulation time the usual Calcium-oxysterol medication was given, together with iron in massive doses. In nine months traces of the attack had disappeared, but soon pronounced hemorrhagic diathesis with thrombopenia (a count of about 8,000) set in. The patient was hospitalized and given blood transfusion, intramuscular injections of blood, calcium and iron. After one month a latent stage was reached when it was felt that splenectomy could be done with the least possible risk. There was moderate postoperative shock, however, and hemostasis was difficult. The patient has since been well, and the postoperative increase in thrombocytes persists after one year's observation (a count of 765,100).

Norsk Magasin for Lægevidenskapen, Oslo

*So-Called Primary Chronic Appendicitis as Symptom in System Disease Study of Etiology and Pathogenesis M. Kobro — p. 856
Scattered Remarks on Hormones and Vitamins E. Poulsson — p. 886

Typhoid Carriers on West Coast of Norway—Vogelsang and Haaland report on seventeen new chronic typhoid (paratyphoid B) carriers. Elimination of bacteria has definitely ceased in four of the five cases treated with cholecystectomy and whose observation period has been long enough to show the results. In one of the previously reported instances, spontaneous recovery seems to have occurred between fourteen and twenty-nine months after infection.

So-Called Primary Chronic Appendicitis—Kobro says that in cases presenting pain in the right iliac fossa designated as primary chronic appendicitis there is often an incongruity between the microscopic lymphocyte infiltration of the vermiform process and the symptoms. In 219 cases of primary chronic appendicitis the most common symptoms were dyspepsia, constipation, dysuria and dysmenorrhea with frequent bradycardia. In twenty other cases there were bradycardia, respiratory arrhythmia, Aschner's reflex, increased dermographism and hyperhidrosis pointing to a disturbance of the vegetative nervous system, especially vagotonia. Investigations show that the vagotonia persists long after appendectomy. The author therefore thinks it possible that vagotonia is the central factor in primary chronic appendicitis, intestinal spasms being the real cause of the pain in a large number of these cases.

POSTMORTEM EXAMINATIONS

METHOD OF OBTAINING PERMISSION

WILLIAM J. HOFFMAN, M.D.

Clinical Fellow in Cancer Research, Memorial Hospital

NEW YORK

The importance of obtaining a high percentage of autopsies on the bodies of patients who die in hospitals needs no emphasis. Adequate instruction of students, development and evaluation of new methods of treatment, verification of diagnoses, accumulation of accurate records and statistics, and furtherance of research are best accomplished in institutions where a large percentage of deceased patients come to necropsy.

Hospitals which require a signed permission for autopsy as a prerequisite to admission have no difficulty in maintaining a high percentage. A different situation prevails in those hospitals which do not enforce such a requirement. These institutions (they constitute a majority of all hospitals) must depend on persuasion.

The request for permission to perform an autopsy must necessarily be made when the relatives are keyed to a high pitch of emotional excitement, when tender sentiments evoked by death offer strong opposition to any procedure which will entail indignity or mutilation to the body of the loved one. Against such a request are instantly marshaled powerful objections of a sentimental, personal or religious nature. To be successful the effort must be backed by appeals based on ethical and practical reasons known to the profession but inadequately realized by the public. These will be most effective if presented by a personality combining dignity, tactful sympathy and absolute sincerity.

The doctor making the request is in a favorable psychologic position. He is one of an honorable profession whose members for centuries have battled sickness and death. To him has fallen a heritage of prestige compounded of gratitude and respect—the intangible legacy from the medical giants of the past. Thorough awareness of this will confer on him a dignity out of all proportion to his age and lend to his arguments a convincing sincerity. The family already feel indebted to him and to the hospital staff for the care given to the patient and despite the repugnance aroused by his request realize that he is pleading a noble cause—the opportunity to carry on with their permission and cooperation the battle to save those similarly afflicted.

This grateful confidence exhibited by the patients and their relatives is the best asset and strongest argument possessed by the pleader. The degree to which it is developed during the patient's stay in the hospital will

determine the likelihood of an autopsy should death intervene. Everything which fosters that sentiment will favorably influence the decision, anything which disturbs it will militate against such permission.

Analysis of the cases in which autopsy was refused revealed the following reasons for failure:

1 **Divided responsibility.** One or more members of the resident staff assumed that some one else was attending to the matter with the result that no one made the request.

2 **Delay.** Relatives had left the hospital by the time the doctor arrived, relatives, anticipating such a request left the hospital hurriedly. The interview was delayed until the following day. Meanwhile the family had discussed the subject at home and decided against it.

3 **Poor technic.** This consists of a sudden brusque request, a high-pressure argument, an unsympathetic manner, loss of temper, threats, refusal to sign the death certificate, a request timidly and diffidently presented, unattractive personality of the doctor making the request, an interview in busy corridor and repeatedly interrupted so that the effectiveness of the argument was lost.

4 **Indecision.** Relatives, unwilling to assume responsibility of granting such permission (though not personally opposed to the autopsy), went home to consult others but did not return.

5 **Professional objections,** made by doctors, dentists, nurses, undertakers or their families.

6 **Personality conflicts.** These comprised dislike of the doctor making the request, dissatisfaction with the patient's treatment while in the hospital, antagonism because of real or fancied discourtesy by the doctor, nurse or a hospital employee, belief that the patient was neglected during his last hours (no doctor was present when the patient died and an intern did not arrive until fifteen minutes later), resentment because relatives were not called to the bedside until too late to see the patient alive, antagonism because the patient did not receive the last sacrament before death.

7 **Religious objections.** Jewish families frequently stated that their religion forbade postmortem examination while others objected to any delay, saying that burial was required within twenty-four hours after death.

8 **Miscellaneous.** These were a previous unhappy experience when a friend or relative had been submitted to autopsy and the body delivered in poor condition, the presence of too many relatives to afford their unanimous consent, a refusal based on one or more of the following objections:

I know, but I'd rather not permit it. Let some one else do it.

It will disfigure the body.

But even such an incision is a mutilation.

This is an ordinary case. You could never learn anything new from it.

But cancer is hopeless. An autopsy would benefit no one.

I do not think she would have wanted me to consent.

He has suffered enough.

To avoid these causes of failure, I instituted the following procedure at the Memorial Hospital for Cancer and Allied Diseases:

Single Responsibility.—The obtaining of permission for autopsy was made the sole responsibility of the

resident surgeon (myself) and carried to the point of recalling him to the hospital at any hour of the day or night whenever a patient died. No one else was permitted to broach the subject to the relatives except in certain circumstances where it seemed probable that the attending surgeon would be more likely to succeed.

Prompt Notification—Patients were placed on the critical list somewhat earlier than had been customary, so that the family was notified in ample time to reach the bedside. Special visiting privileges were thus extended to the relatives often for several days before death occurred.

Courtesy—Cultivation of a friendly spirit between the relatives and the hospital personnel was emphasized. Telephone inquiries concerning the patient were referred to the resident surgeon and, if thought advisable, a report was furnished. A courteous, frank statement as to the patient's condition prior to death often proved to be the approach to a friendly consideration of the request for an autopsy. An occasional special visiting privilege granted to a relative adds little to the work of the nurses and much to the gratitude of the recipient.

Accessibility—Half an hour was set aside each afternoon and evening immediately after the visiting hours, at which time the relatives could meet the resident surgeon and receive a frank appraisal of the patient's condition, with a prognosis and a discussion of treatment or other aspects of the case. At these meetings the relatives could not fail to be impressed with the amount of effort expended in examining, diagnosing and treating each patient, and the industry, patience and kindness of the nursing staff. Many of them lost their obvious fear of the hospital as a vague, impersonal mechanism, and felt that the patient was in the kindly hands of friends. When death appeared to be only a matter of hours, the relatives again were notified and the family clergyman summoned. The frequent visits of the intern and the resident surgeon during these last hours offered further evidence that no resource of medical science was omitted in an effort to prolong the patient's life.

PLAN OF SOLICITATION

Request for autopsy is never made in the patient's room or in the ward. Such a request is best made in a part of the hospital not too intimately associated with the deceased person and among surroundings calculated to lend an air of grave responsibility and dignity to the interview. Further, a white uniform is not an asset to such a discussion. To many it is the badge of immaturity, the mark of an undergraduate clinical clerk. The interview is more likely to be successful if the doctor wears a business suit with or without the long white coat associated in the layman's mind with the maturity of an attending surgeon.

After a patient has died and the relatives have recovered from their first expression of grief, they are taken in charge by the nurse and brought to meet the resident surgeon at the office of the clinical director. In conducting the interview the doctor's manner should unite dignity, responsibility and sympathy. No reference to the purpose of the meeting should be made. The subject should arise apparently without premeditation, and in most instances the talk can be guided around to it so that it will be broached by the family. Their first question will be a desire to know why they have been brought there. The usual reply is "I

have sent for you to ask if I can help you in any way. Are there any questions you would like to ask about this patient?" They will usually wish to discuss the case in some detail. With the history of the patient before one, it is worth while to answer their direct questions. A few minutes may suffice to form a quick estimate of the psychological types among the members of the family. It quickly becomes apparent which one is the dominant personality in the group, and it is on this person that one's attention must be concentrated and toward whom most of the conversation must be directed. The salient points of the case should be illustrated from the chart. A concise summary should be presented in nontechnical language. This should include the possible etiologic factors, familial tendency or hereditary character, course of the disease, reason for operating, operative observations, pathologic report and postoperative course leading to the patient's death. Each of these aspects of the case presents mysterious elements. These may stir the relatives' curiosity enough to influence them to permit an autopsy for their elucidation. This summary may require about fifteen minutes. It is time well spent. It probably is the first time that the assembled family have had a clear conception of the patient's trouble and any accurate knowledge of what the doctor tried to accomplish. The vague resentment because the patient died is transformed into gratitude to the doctors for the effort they made to save him.

During this discussion the relatives will ask questions as to the etiology, extent of the disease, explanation of certain symptoms and actual cause of death. Many of these cannot be answered with absolute certainty, and the frank recital of the limited knowledge on these points in the case of this particular patient should be qualified by the statement, "What I have told you is my clinical opinion, what I believe we would find if we were to make an examination." At this point the battle is joined. Any objection to such procedure is now made evident. One relative strongly opposed to autopsy can quickly bring the others to his side. Opposition must be met swiftly or all is lost. The effectiveness of the different arguments in favor of autopsy varies according to the psychologic mechanisms of the person to be convinced. It varies, therefore, according to age, sex, nationality, religion, education, past experience, prejudices and personality. On the accuracy with which one discovers these peculiarities depends the ability to select the appropriate argument, and thus to a great degree determines the chance of success. The ability to anticipate certain objections and eliminate them before they have been expressed enables one to prevent the implantation of a doubt in the minds of those heretofore favoring an autopsy. To do this one must watch them closely to detect evidences of conviction or opposition. It is sometimes best to maintain control of the discussion until the greater part of the argument has been presented, at other times, where the opposition is not too pronounced, it is better to let them talk. This is a delicate point, and confidence can be gained or lost by either step, depending on the correctness of one's judgment.

ARGUMENTS IN FAVOR OF AUTOPSY

Duty to Humanity—Each person owes a duty to humanity to permit the postmortem study of the bodies of those who die. Medical science has reached its present high level of development because of the opportunities afforded for such study in the past. The increased average span of life today was purchased by the sacri-

fices of our forebears. We of the present generation must not halt this progress.

Determination of the Cause of Death—The cause of death can be accurately determined. This is important to the family because of its bearing on familial or hereditary disease, cancer and occupational hazards and diseases or its relation to previous injuries, illnesses and operations. If there is any familial tendency to a particular disease, it should be discovered so that prophylactic measures may be taken to protect the children. It is of practical importance because it satisfies the insurance company of the true cause of death and serves to obviate litigation or delay in settlement. It will provide more accurate vital statistics, and improve the diagnostic ability of the doctors.

Extent of Disease—This can be established and the cause of certain obscure symptoms discovered. Autopsy will thus disclose whether these were related to a single disease or to two or more separate pathologic processes.

Medicolegal Cases—If one expects to bring suit to prove that this patient developed the disease from which he died as the result of injuries due to another's negligence, the best way to establish that contention is a thorough postmortem examination. The other party to the suit similarly may apply for a court order compelling such an autopsy. It is better for your contention that it be done here by a trained specialist so that his report may become a part of the deceased patient's hospital record.

Postmortem Examinations Not Unusual—The practice is growing rapidly in America. In many countries it is compulsory. More than three quarters of the patients who die in this hospital are submitted to such examination. It is not limited to the poor and obscure; consent is just as readily obtained from the families of our private patients. Most great men are examined post mortem: Columbus, Napoleon, Lincoln, Garfield, McKinley and others.

Rarity of the Disease (when this is actually true)—The condition from which the patient died is one of great rarity. It is little understood. There have been no recorded cures. At the present time any one who develops this disease inevitably succumbs to it. So few cases occur that doctors have not had the opportunity to make a thorough study of it. It is imperative that every such case be thoroughly investigated so that eventually a cure may be found.

Aid to Research—This is a research institution devoted to the study of tumors. Its clinical, radiologic, surgical, biologic, chemical, physical and pathologic departments are devoted to increasing our knowledge of these diseases. Generous gifts have supplied funds, equipment and trained personnel to that end. It is our privilege and solemn responsibility to provide the most necessary element—that one thing which money cannot buy—the actual material for study.

Evaluation of Treatment—The patient was treated according to a technique which is still in the process of development. Some of the patients with similar disease treated by this means have been greatly benefited, and many are alive and have been apparently free from disease for nearly two years. But this death represents one of our many failures. Why did he die and these other patients recover? Would a change in our technique have produced a happier result? The only way that we ever shall work out the best method of treatment is by a study of those whom we fail to save.

COUNTER-ARGUMENTS AND THEIR REFUTATION

1 "I know, but I'd rather not permit it. Let some one else do it."

"Because for many centuries people refused such permission, medicine made no advance. Much progress remains to be made. Had we learned, from examinations made in the past, how to recognize the early clinical signs of this disease, your mother might have been saved."

2 "It will disfigure the body."

"The examination is done by a skilled specialist through a surgical incision which afterward is closed, as in an operation. The appearance of the body is enhanced rather than injured. Discoloration from the accumulation of blood is avoided. The drainage of this blood and the removal of clots from the vessels permits better circulation of the embalming fluid and results in better preservation of the body. Your undertaker will verify this for you if he is asked."

3 "But even such an incision is a mutilation."

"It is, but the mutilation, as you call it, is an ethical procedure carried out with proper respect for the dead, for the ultimate benefit of humanity."

4 "This is an ordinary case. You could never learn anything new from it."

"That is something no one can ever say. Many important observations and even great discoveries have come from cases which seemed in no way unusual."

5 "But cancer is hopeless. An autopsy would benefit no one."

"There are more than a thousand cases of cancer apparently cured more than five years among the patients of this hospital. The methods employed in treating these successful cases were developed by the study of just such cases as this."

6 "I do not think she would have wanted me to consent."

"I should not want you to consent unless you believed that she would have been eager to do this much to help those afflicted as she was."

7 "He has suffered enough."

"What we would do would not add to his sufferings. Let us be thankful that they are ended. But thousands of other human beings at this present moment are suffering as he did. How happy he would be if he could know that your consent might preserve someone else from similar misery."

8 "We are orthodox Jews and our religion forbids autopsies."

"The law in reference to autopsies among Jews has been discussed by many eminent Jewish leaders. Rabbi B. L. Levinthal of Philadelphia (quoted by Hammond¹) has given his full approval to postmortem examination. He said 'I desire to state unquestionably that the dissection of a corpse is not prohibited under the Jewish Rabbinc Law where a reputable physician believes that it is essential for the advancement of medical science. Where a postmortem examination may result in the discovery of the origin or cause of some serious disease, it is my firm conviction that thus to serve humanity is sanctifying rather than desecrating the dead.' The present chief rabbi² of the orthodox community of Jerusalem is on record as giving consent to postmortem examination."

'Dr. Jacob Z. Lauterbach,³ an important Jewish scholar, stated that the only possible objection to postmortem examination would be based on an ancient Biblical law (Deuteronomy 21:23) recommending burial on the same day on which death occurred but that to the practice of autopsy as such one cannot find any express objection in the Talmud.' The following is quoted from his paper:

'The supposition that a postmortem examination constitutes a disgrace to the human body has no real basis in Jewish literature. It is true that the Talmud assumes that to dissect and examine a dead body might be considered a

¹ Hammond, F. C. Overcoming Opposition to Autopsies. *Mod Hosp* 25:333, 1925.

² Report of Committee on Postmortem Examinations of the American Hospital Association, 1930.

³ Lauterbach, Jacob Z. *American Israelite* Nov. 19, 1925.

disgrace to that body, which, of course, should be avoided. This, however, holds only in cases where it is done unnecessarily or for no good purpose. For in the same passage in the Talmud it is taken for granted that if such postmortem examination might possibly result in saving another man's life, we should by all means dissect and examine the dead body, so that we may possibly avoid the loss of another life.

"According to the Talmudic Rabbinic Law, all the laws of the Torah, excepting those against idolatry, incest and murder, may and should be violated, if necessary, for the saving of human life. According to this law, even if there were found a law prohibiting the dissecting of a human body, it would have to be ignored in favor of autopsy, which might lead to the saving of a human life."

"Dr. Charles D. Spivak,⁴ a noted Jewish scholar of Denver, has summarized the law as follows: 1. Autopsies are not permitted when they are an indignity to the dead. 2. Autopsies are permitted when they are an honor to the dead. 3. Autopsies are permitted when a human life can be saved thereby, for instance, when there is present a sick man who suffers from the same malady from which the deceased died. 4. Autopsies are not permitted for purely experimental purposes, i. e., when the sick are not before our eyes."

"In this hospital, we have many patients suffering from the same disease. We are seeking a cure. To serve in any way to save these 'sick before our eyes' is not an indignity, it is an honor to the dead. Jewish hospitals like Mount Sinai, Montefiore and Michael Reese maintain a high percentage of postmortem examinations on their Jewish patients and are supported and encouraged to do so by the leaders of the Jewish faith."

MISTAKES TO BE AVOIDED

Before talking to the relatives it is important to review the deceased patient's history so as to be familiar with the details of the case. The value is twofold, a general plan of argument can be outlined, based on whatever unusual features of the case justify a postmortem examination, further, one avoids the betrayal of ignorance of the case and the development of any suspicion that the doctor's sole interest is to secure the body for experimentation.

Delay should be avoided. The most favorable time to make the request is usually from about fifteen minutes to half an hour after the patient has died. This is sufficient time to permit recovery from their first expression of grief and is too soon to allow vaguely formulated ideas of opposition to become too firmly rooted.

It is unwise to entrust the negotiations to lay friends of the family. Despite their best intentions, failure is the rule. No layman commands the respect accorded the doctor, nor can he so well present the arguments for a postmortem examination. Neither is he likely to prove sufficiently alert, persistent or persuasive in counter-argument to overcome the family's objections. It is helpful, however, to have the friend present at the interview to second the doctor's argument with a nod of assent and approval or an occasional word of gentle urging.

Interpreters are unreliable. The same objections prevail here as in the case of the family friend, with the additional disadvantage that one cannot understand the interpreter's attempt to present the case to the family. The argument suffers grievously in translation by garbling, abbreviation and the interjection of the interpreter's personal feelings in the matter. It is preferable to employ a member of the house or visiting staff familiar with the language.

Unanimous consent of a large group of relatives is most difficult to obtain. A better plan is to select the strongest personality among them and talk to him privately. When he is thoroughly convinced, he may be delegated to persuade the others.

The interview should be characterized by quiet, unhurried dignity. The family should feel that the solicitor is there as a kindly, sympathetic friend to assist them with the final care of their loved one. High pressure argument, antagonism and quarreling have no place in this discussion and defeat its purpose. Unreasonable opposition must be disarmed by patient explanation which avoids giving offense or too much concession to an ignorant or antagonistic person. Loss of temper entails loss of respect and certain failure.

An impression of callous scientific curiosity may be created if permission for an autopsy is solicited before the patient has died. In general it should be avoided. It affords the family time to discuss the matter at home, where they are likely to decide definitely against it. One should, however, discuss the puzzling features of the case so as to prepare their minds for the suggestion of an examination to clear up these questions.

Euphemism of terms should be employed. It is better to avoid the use of words with gruesome connotations. For "autopsy," "inquest" or "necropsy," where possible, one should substitute "examination of the body." The family can be made aware of what is intended without receiving an impression of mutilation and horror. The difference between a postmortem examination and an anatomic dissection should be made clear.

At first one should make no direct reference to the extent of the autopsy to be done. In a majority of cases a complete examination will be permitted. The greatest opposition, naturally, is against opening the skull. When reluctance is apparent, it is better (unless special features of the case indicate that an examination of the skull would be of value) to intimate that, of course, the examination will be limited to the organs of body cavities and that the head and face will not be disturbed. It is important that the doctor make this statement before the family has voiced this objection, else his reassurance becomes a concession that savors of bargaining. Partial examination or inspection of wounds may be requested if more extensive procedures are refused. The family should be invited to return in two weeks to receive a copy of the autopsy report and to discuss its significance.

Professional Objections—Doctors, dentists, nurses, undertakers and their relatives sometimes object to autopsies because of hearsay or personal experience with autopsies featured by carelessness, irreverence or disregard for the subsequent appearance of the body. It is helpful to have the pathologist at hand to give his assurance that he will personally perform the examination and to convince them that every precaution will be taken to improve the appearance and preservation of the body. Once this has been accomplished, one may employ whichever of the foregoing arguments are applicable to the case to convince the relatives of the necessity for the examination. The family should be reminded of the many instances of self-sacrifice in the life of the deceased and how appropriate it is that this last worldly contact should be a final act of altruism. If reluctance is still evident, one is justified in inviting the professional member of the family to attend the examination. This offer rarely is accepted although consent often is won by this evidence of good faith.

⁴ Spivak, C. D. Postmortem Examination Among the Jews. New York M. J. 96: 1185-1189 (June 13) 1914.

Additional Assistance—Catholics grant a high percentage of autopsies. Their objections are usually based on sentiment. When difficulty is encountered, the parish priest can be relied on to aid in obtaining permission.

The family physician is a potent force and, if invited, will usually exert his influence with the family. The assurance that he will be present at the examination may obtain their consent.

When matters seem difficult, it is well to remind the family how the attending physician strove to aid the patient, how disappointed he was when he failed and how much it would mean to him to be allowed to verify his diagnosis, to make certain that everything possible had been done for the patient and to increase his knowledge of such cases so that the next one might end more favorably. If still reluctant, the doctor mentioned should be called to emphasize these points in person.

SOLICITATION BY TELEGRAPH

When no relatives are present at the time of death a telegram should be sent to the next of kin recorded on the patient's history. In a splendid article on the subject, Mills⁵ suggested the following wording:

Mr. _____ died (suddenly) this morning. Not necessary to come. We can make all arrangements. Wire complete instructions for embalming and shipping. State limit of expenditure for furnishings. Important to authorize examination of the body.
(Signed) _____ M.D.

In case the reply omits the permission a second message is suggested as follows:

Instructions received, will execute them fully. Undertaker (mention name) will communicate direct. Government expects accurate diagnosis for death certificate. Clinical diagnosis inadequate. Please wire consent for examination collect. Body not disfigured, preservation improved.
(Signed) _____ M.D. (same name as that used before)

COOPERATION WITH UNDERTAKER

The undertaker usually will lend his support by reassuring the family that the procedure will not interfere with the embalming process or with the appearance of the body. Points of importance in developing and holding his loyalty are the following:

Conservation of the undertaker's time by prompt delivery of the death certificate to him, by performance of the autopsy as soon after death as possible and by delivery of the body to him at a specified time.

Careful restoration of the body to as nearly normal condition as possible by keeping the head and shoulders raised so as to facilitate the drainage of blood, limiting the incisions to the requirements of the case (from the suprasternal notch to the pubis in men, from beneath the breasts to the midline to the pubis in women). The circulation of the head and arms should be kept intact by ligating the left carotid, left subclavian and innominate arteries. The stumps of the esophagus, trachea and rectum should be tied off so as to prevent leakage. If the brain is removed the carotids should be ligated within the cranium and the cavity filled with plaster of paris; there should be careful approximation of the skull cap so as to prevent displacement. The head and face should be protected so that pressure marks are not produced. The undertaker should be afforded the use of the morgue where he may embalm the body.

RESULTS

The foregoing procedure in soliciting permission for postmortem examination was established at the Memorial Hospital on July 1, 1932. During the preceding six months (from January 1 to June 30) there were

fifty-eight hospital deaths. From this number of possibilities twenty-seven autopsies were obtained. The monthly percentage varied from 14 to 62.5, and the average for the six months period was 46.5. Twelve of these patients were Jewish, from which number, one permission for autopsy was obtained (8.3 per cent).

During the next six months (from July 1 to December 31, during my incumbency), there were seventy-one deaths in the hospital. Relatives of three of these patients could not be located, so that there was no opportunity to solicit permission for autopsy. Fifty-six autopsies were obtained from this group of sixty-eight cases by the method described. Two of the deceased patients came from distant cities. Permission was requested by telegraph and consent obtained for both. Four families were solicited by telephone, and three of them consented to the examination. The monthly percentage varied from 71.4 to 100, and the average for the six months period was 82.3.

Sixteen patients were Jewish, in which group ten autopsies were granted. Fifty-two patients were Christians, from which number forty-six autopsies were

Autopsy record of the Memorial Hospital for 1932. The open squares indicate autopsies refused; the black squares, autopsies obtained.

secured. The Jewish group constituted 24 per cent of the total number and yielded an autopsy percentage of 62.5. The Christian group constituted 76 per cent of the total number and granted 89 per cent of autopsies. The rate among the Jewish patients was about two-thirds that of the others, but the figure (62.5 per cent) given constituted a sevenfold increase over the preceding six months, an improvement ascribed to tactful handling of the family and the religious question involved. As shown in table 1, there were 32 Protestant families, with 27 autopsies (84 per cent), and 20 Catholic families, with 19 autopsies (95 per cent).

Table 2 analyzes the effect which the kinship of the person solicited has on the percentage of autopsies granted. The percentage figures are so high that they do not reflect the variations in difficulty encountered. In general, the closer the relationship, the greater will be the objection to autopsy. Men as a rule, take a broader and more impersonal view and usually are more reasonable and less skeptical of human motives than are women. Experience reveals that husbands, fathers, brothers and sons present less difficulty than do the corresponding feminine relatives. Nevertheless, tactful

⁵ Mills, Ralph C. Means of Securing Post Mortem Examination. Bull. Am. Coll. Surgeons 14: 40-57 (Dec) 1920.

persuasion and persistence usually prevail. Thus one notes that nearly equal numbers of autopsies were obtained from both sexes, twenty-nine from male relatives and twenty-seven from female relatives.

All Germans, Danes, Irish, Negroes and all Italians but one consented to autopsy. Six Jews refused because of religious and sentimental reasons. Six Christians withheld permission, three because of sentiment, one because of previous unsatisfactory experience with autopsies and one because the patient had exacted a promise not to permit it. One other attempt failed because it was impossible to obtain unanimity among thirteen assembled relatives.

Search for the most potent reason impelling consent to autopsy leads to the conviction that in most instances it is based on gratitude. This is cultivated during the patient's stay in the hospital by numerous instances of kindness and consideration. It is roused to its greatest power at the interview by the sincere, sympathetic and skilful persuasion of the solicitor. A high percentage of autopsies obtained in this manner testifies not only to the efficiency and scientific interest of the hospital

TABLE 1—*Religious Composition of Families Solicited*

Religion	Number	Autopsies	Percentage
Christian	52	46	89.0
Protestant	32	27	84.0
Catholic	20	19	95.0
Jewish	10	10	62.5

SUMMARY

The importance of autopsies in the instruction of students, development of new methods of treatment, verification of diagnoses, accumulation of accurate statistics and furtherance of research is emphasized.

The reasons underlying failure to obtain permission for postmortem examination are classified and discussed. A detailed plan of solicitation is described. This procedure is based on unity of responsibility for securing permission for autopsy, cultivation of friendly relations between the family and the hospital personnel, a courteous and frank statement of the patient's condition while in the hospital, a prompt approach to the family after the death of the patient, a dignified, kindly and sincerely sympathetic manner during the interview, a frank discussion of the case, a tactful presentation of arguments for autopsy found by experience to be effective and the counter-arguments designed to refute the objections raised by the family. These arguments and counter-arguments are summarized, including expressions from leaders of the Jewish religion favoring postmortem examination and disavowing the frequently heard statement that autopsies are forbidden by Jewish rabbinic law.

The results of this plan of solicitation are reported. Prior to the development and adoption of this procedure, the percentage of autopsies at the Memorial Hospital was 46.5. During the six months period following the development of this plan the percentage of autopsies was nearly doubled. The monthly averages varied from 71 to 100 per cent, the average for the whole period being 82.3 per cent. The percentage of autopsies obtained from Jewish families was increased nearly sevenfold (from 8.3 to 62.5). Christians granted permission for postmortem examination in 89 per cent of cases.

Regardless of nationality, race or religion, the chief reason impelling consent to autopsy was the family's gratitude for numerous acts of kindness and consideration, roused to its greatest power by the sincere sympathy and skilful persuasion of the solicitor.

ABSTRACT OF DISCUSSION

DR. F. W. HARTMAN, Detroit. Dr. Hoffman's suggestion that the resident is a good person to obtain the permission is excellent. When the younger men are allowed to obtain permission it is along the latter part of their intern year that they begin to get a high percentage of examinations. In some places this function is left to an organization in the department of pathology, and that is very successful because it is continuous over a period of months or years. Wherever the responsibility is placed, the percentage of autopsies will be in direct proportion to the feeling of the head of the department. If that chief is not enthusiastic and insistent on autopsies the chances are that the percentage from his department will fall down. Next in importance for obtaining autopsies is the undertaker, who frequently makes the contact within half an hour or an hour after death. The antagonism of the undertaker frequently prevents the permission being obtained. It isn't the intelligent well informed undertaker, but one who is poorly educated, not so sure of his technique, that is afraid to embalm a body after a necropsy. I have found that the best way to bring this type of undertaker into line is for the pathologist to make some sort of contact with the undertakers' organizations, talk over the problems in common meeting and make some tentative agreement as to what shall be done and how it shall be done. A grievance committee may be established composed partly of pathologists and partly of undertakers, so that misunderstandings may be thrashed out and so that uncooperative undertakers may be brought into line. Dr. Hoffman laid emphasis on the clinical diagnosis and on letting the patient's relative know that perhaps the clinical diagnosis was not satisfactory. I think that is dangerous in many cases. The clinicians frequently will construe it as a reflection on their work, and the patient's relative will frequently come back for a complete review of the case. It is always well to avoid that argument if possible.

DR. ISRAEL DAVIDSOHN, Chicago. Dr. Hoffman emphasized that by the use of proper procedures the increase of permissions was striking, even among Jewish patients. In the experience of those familiar with conditions in Jewish hospitals, that is not unique. The percentage of postmortems in institutions such as the Mount Sinai Hospital in New York and the Michael Reese Hospital in Chicago compares favorably with other hospitals of similar standing. In the Mount Sinai Hospital in Philadelphia, with 78 per cent of Jewish patients, a low percentage of permissions was obtained until 1927, when, as a result of a campaign the proportion began to rise rapidly till it surpassed 60 per cent in 1930 when I left Philadelphia. The increase has been continuing steadily. The Mount Sinai Hospital in Chicago with about 99 per cent of Jewish patients was dropped early in 1930 from the list of hospitals approved for internship by the American Medical Association on account of its low percentage of postmortem examination. As a result of effort on the part of the administration and the staff, the percentage was raised and the hospital was promptly reinstated. It is fair to conclude that the opinion that it is extremely difficult to get permissions for postmortem examinations from Jewish patients is not well borne out by facts. A few words

about the obstacles encountered while attempting to raise the percentage of postmortems. Pathologists can share in arousing greater interest in postmortems among physicians by laying greater stress on the correlation of the clinical and pathologic aspects of the postmortem observations. During our campaign in Philadelphia, the members of the attending staff signed permissions for postmortems on themselves. The presentation of such a permission has not infrequently been the most potent argument. We have also found that procedure of great help in Chicago.

DR WILLIAM J. HOFFMAN, New York. In regard to the discussion by Dr Hartman. In New York a joint committee has been formed consisting of members from the New York Academy of Medicine, the New York Pathological Society and the Metropolitan Funeral Directors Association. Cordial relations prevail among these groups and a code has been drawn up embodying suggestions for close cooperation between hospital authorities and funeral directors. Posters containing these suggestions are sent to all hospitals and are displayed in the autopsy rooms of the hospitals. The poster contains a diagram of the incisions that are approved by the undertakers and contains a list of nine technical suggestions which contribute to the better preservation of the body and aid the undertaker to improve its appearance. The discussion of the clinical diagnosis with the families of patients in general hospitals must be conducted with great caution, lest one seem to question the diagnosis of the attending physician. In a special cancer hospital this danger is less serious because the family has usually been already informed that the patient had cancer. The final pathologic diagnosis which the family receives after the autopsy is simply an elaboration of what has already been told. It sometimes includes, in addition, an explanation of certain terminal phenomena that the clinician himself was unable to explain during the illness of the patient. I agree with Dr Hartman that the matter must be handled with great delicacy.

PRESENT STATUS OF THE BIOPSY

A. B. McGRAW, M.D.

AND

F. W. HARTMAN, M.D.

DETROIT

Notwithstanding the advances which are steadily taking place in knowledge of the chemistry, serologic nature and biology of tumors, gross morphology and, more especially, microscopic morphology remain our best means of determining their histogenesis, classification, activity and prognosis. The diagnostic application of this morphologic knowledge lies in the procedure known as biopsy. Though this word strictly includes the removal of any tissue from a living subject for diagnostic examination, usage has tended to confine it to the examination of tumor tissue suspected of having malignant qualities.

About the middle of the nineteenth century the idea of biopsy began to be voiced in independent reports or suggestions by various authors here and abroad, among them Sedillot¹, Maruy² and Lebert³ in France, Hannover⁴ in Denmark and Donaldson⁵ in this country. It was Virchow,⁶ however, who first laid the rational

foundation of the procedure as a diagnostic aid to treatment when, in 1854, he demonstrated microscopically that excision was the proper treatment for malignant tumors because of the possibility of their complete eradication in the early localized stage of the disease. Later on Virchow⁷ became skeptical regarding the superiority of microscopic to gross pathologic diagnosis, and so great was his authority that satisfactory progress in the use or development of the biopsy was greatly hindered. True recognition of its value and possibilities came early in this century owing largely to the pioneer work of Wilson⁸ and the numerous carefully reasoned articles of Bloodgood,⁹ Ewing,¹⁰ MacCarty¹¹ and Wood¹². Concurrent efforts made to educate, through publicity, both the laity and the medical profession regarding cancer began more and more to bring early and often doubtful lesions to the attention of physicians, and this helped to stimulate interest and effort in earlier and more accurate diagnosis of tumors. In 1917 the question of biopsy was brought to a controversial focus through offers of the New York City Board of Health and the Cancer Committee of Harvard University of free microscopic diagnosis on pieces of tissue submitted by practitioners. This offer had the support of the American Society for the Control of Cancer¹³ and of well known pathologists, but in some quarters it was bitterly denounced. The opinion of a qualified group of surgeons, as collected and tabulated by Greenough,¹⁴ was divided, but was generally in favor of biopsy with certain restrictions and conditions.

Among various objections to biopsy, two were mainly raised. One alleged that incision of a malignant tumor stimulates local growth, the other that incision disseminates tumor cells. The first of these objections had already been answered by the experimental work of Tyzzer¹⁵ and Lubarsch,¹⁶ and later in Knox's¹⁷ review of the subject of the relation of trauma to the occurrence and growth of tumors. Experiments conducted by Nather¹⁸ and interpreted as indicating an increase

of tumor growth following incision are not convincing. The second objection has been answered satisfactorily by Wood¹⁹ as far as biopsy on experimental tumors is concerned. In two large groups of rats, simultaneously inoculated with one of two varieties of sarcoma normally prone to produce metastases, he found no more metastases in the biopsied rats than in those whose tumors were excised on the day the biopsy was made. On the other hand, Knox²⁰ and Tyzzer¹⁵ showed independently that massage of mouse or rat tumors forced showers of tumor cell emboli into the lungs and greatly increased the incidence of metastases. On the clinical side, a satisfactory refutation of the numerous reports in the medical literature of isolated cases or small series of various misfortunes following biopsy is made in the statement of Roux-Berger²¹. In a consecutive series of 825 cases of lingual cancer reported from the Curie Institute of Paris, where no patients are treated without biopsy, he found no evidence of harm from the careful diagnostic excision of tissue.

Advances in methods of rapidly sectioning and staining biopsy material have been developed in this country mainly by Wilson, MacCarty and Bloodgood in the application of the freezing microtome to fresh unfixed tissue, by Warthin²² in his twenty-four hour method for quick fixation, embedding, sectioning and staining, and by Terry²³ in the surface staining of fresh unfixed, thick sections examined by transmitted light. In the foreign literature E. H. Shaw²⁴ reported a method not unlike Wilson's, and Hoffheinz²⁵ favored the older method of quick fixation in hot formaldehyde before freezing and sectioning. Dudgeon and Patrick²⁶ reported satisfactory results from stained films of surface scrapings from incised tumors. Dengler²⁷ advocated teased-out bits of tissue coverslipped and treated with 1 per cent acetic acid to accentuate cell detail. Schultz-Brauns²⁸ has made the ingenious suggestion that maintaining the low temperature of a thin frozen section by using a thoroughly chilled microtome knife causes such firm and unwrinkled adhesion to a glass slide that staining is both facilitated and improved. Leroux²⁹ described surface illumination of surface-stained thick sections by a small electric bulb built into and operating through the objective of the microscope. Mandelbaum,³⁰ Quesnel³¹ and Zemansky³² have each described ingenious methods for fixing and staining the cells of pleural and peritoneal exudates.

Within the past few years in addition to numerous articles restricted to the application of the biopsy in

some special field, comprehensive surveys of the entire question with extensive bibliographies have appeared in the German literature by Baumecker³³ and Batzdorff,³⁴ in the French by Robert³⁵ and recently in the American literature by Hellwig³⁶. In spite of all this published material, there are certain aspects of biopsies which may properly be emphasized at this time.

THE RELATION OF BIOPSY TO OTHER DIAGNOSTIC PROCEDURES

Although the general clinical aspect of cancer is by no means a completely explored territory, it is sometimes a neglected one. Not only is this true of deep-seated or obscure growths, but it is especially true in the case of small surface lesions in which biopsy information is easily obtained and so often is quickly conclusive. Whether a patient presents a visible, palpable lesion, large or small, or only suggestive symptoms of internal cancer, no form of local examination is properly made without an accompanying clear, searching history and careful general physical examination supplemented by appropriate laboratory investigations. For the local lesion itself, close critical inspection and palpation described in accurately comparable terms are nowhere more important than in malignant conditions. The biopsy should never replace or precede other clinical methods of diagnosis, but should rather be used to supplement them by confirming or disproving the clinical diagnosis, as is the case in all other laboratory procedures. The relation of biopsy to roentgen diagnosis differs from its relation to clinical diagnosis in that the x-ray film frequently offers an entirely different and often satisfactory method of objective diagnosis and permanent record, as in the case of certain tumors of the bone, thus making biopsy unnecessary. Again the relative merits and indications of therapeutic tests in relation to biopsies are matters that have been given comparatively little attention. A therapeutic test in the form of antisyphilitic treatment may be used legitimately in early testicular tumors and certain lesions of the periosteum and bone in the presence of untreated syphilis. In the form of radiation therapy it may be used in suspected Ewing's sarcoma of the bone and in suspected lympho-epithelioma, lymphosarcoma and Hodgkin's disease. In all of the lesions cited the therapeutic test should precede biopsy, and, if prompt response to therapy results, the biopsy may be dispensed with.

COOPERATION BETWEEN WELL TRAINED SURGEONS AND PATHOLOGISTS

Cooperation between surgeons and pathologists is essential for obtaining satisfactory biopsy material. In the first place it is obvious that unless the surgeon has a good knowledge of pathology, he will be unable to recognize and differentiate neoplasms grossly, and he will surely fail frequently in the selection of proper portions of the suspected lesion for microscopic examination. Further, this knowledge of pathology is necessary if the surgeon is to recognize properly the problem of the pathologist. The arbitrary attitude of some surgeons that pathology is a mathematical science in which any trained technician can find the correct answer not only makes the work of the pathologist unpleasant, but

unscientific and often inaccurate. The pathologist, on the other hand, should have a broad training and experience in both gross and microscopic examination, which can be acquired only by the observation of a large amount of fresh surgical material through a period of years.

The pathologist's experience will be particularly helpful to the surgeon if it includes the clinical observations of neoplasms of all kinds. With such experience the pathologist, working at the elbow of the surgeon, can be of great assistance in the gross differential diagnosis of the lesion and in the selection of material for microscopic diagnosis, and can render a far more valuable opinion as to diagnosis and classification. Such cooperation of the surgeon and pathologist is essential for the best results and can be obtained, of course, only when the pathologist is always available during an operation.

OBTAINING BIOPSY MATERIAL

Advances in the technic of obtaining biopsy specimens may be correlated mainly with the development of new instruments. The various endoscopic instruments have made biopsies from the larynx, esophagus, urinary bladder and lower bowel possible, but they have thereby added much to the burdens of the surgeon and pathologist because the material obtained is necessarily limited in amount and, unless properly selected by an operator who has a good knowledge of gross pathologic changes in his particular field, is more apt to give a misleading picture and a false sense of security than an accurate diagnosis. The pathologist, although properly trained, may be led into error not only because of the small size of the tissue obtained, but also because it is too often from the surface of the lesion and does not show adequately the deeper structure of the tumor or its relation to normal surrounding tissue. Further, the pathologist too frequently feels obligated to give an opinion despite the fact that he knows the tissue submitted is inadequate. In this case the greatest service will be rendered by his reserving opinion and requesting more tissue.

The needle puncture method of Martin and Ellis³⁷ and the punch biopsy method of Hoffman³⁸ offer new opportunities of obtaining tissue from deep-lying growths without cutting operations. Their chief applications would seem to be, first, in late lesions in which infection and ulceration might conceivably result from incision, and second in deep-lying lesions in which radiation might be the method of choice in treatment. The general objections to these methods are, first, that to obtain satisfactory specimens considerable special training and practice on the part of the operator are required, and, second that the interpretation of the material obtained imposes like requirements on the pathologist. Those who are competent to diagnose tumor tissues when obtained and prepared in the usual manner will need readjustment of their criteria, as well as additional experience with this particular method, before placing reliance on it.

The cautery loop may be used in place of the knife in obtaining biopsy material but distortion of the tissue from the heat must be avoided. While the white hot cautery loop cuts more like the knife and gives little distortion dull red heat seals lymphatics better but always ruins small bits for microscopic examination.

The higher temperature for excision followed by a lower temperature for sealing the lymphatics and blood vessels seems the best way for employing this method. Similarly, the electrodesiccating current, applied by a narrow blade or a stiff wire loop and followed by electrocoagulation of the denuded surfaces, is an equally useful substitute for excision by a knife. Like the thermal cautery, it has the advantage of applying minimal pressure to tissues in the course of cutting. It is doubtful, however, whether a sharp knife, gently used and followed by chemical cauterization, is essentially less safe than more complicated methods.

The influence of the location and size of a given lesion is frequently the determining factor in the selection and technic of a particular method of biopsy. Foregoing detailed consideration, the following generalizations are submitted as of basic importance. Whenever the size, nature and location of a lesion, whether cutaneous, subcutaneous or mucosal, are such as to admit of its complete and wide removal without mutilation and without resort to major surgical intervention, such complete removal is decidedly preferable to a biopsy. Again, every biopsy, whatever its location, should be conducted with all the care of a major surgical procedure with reference to strict asepsis, sharpness and appropriate selection of instruments, adequate exposure and illumination, and with the greatest precision and gentleness in technic. The danger from frequent or rough palpation of tumors or lymph nodes holds with equal force in the manipulations incidental to removing a biopsy specimen. Lastly, a clear description of its source, its relation thereto and the method by which it was obtained should accompany every biopsy to the pathologist who is to examine it.

SECTIONING AND STAINING OF BIOPSIES

It is not within the province of this paper to discuss the details of sectioning and staining methods, but it is necessary to emphasize the importance of using some method of quick fresh frozen sections followed by a method for permanent fixed preparations. At the present time, the fresh frozen method or vital staining method is necessary to show, as MacCarty has pointed out, the characteristics of the living cells and their relation to each other and to their stroma. Fixed permanent sections—the fixed frozen, the paraffin-embedded or the cellordim-embedded variety—are equally essential as a check on quick sections and for repeated study, review, filing and photomicrography. When tumors prove to be unusually soft and cellular, with relatively little stroma, Warthin's method of quick fixing and embedding may be used to advantage, as a substitute for the frozen section.

Methods vary according to country, locality and institution, but the essential thing is for the pathologist to try various methods as they are proposed without prejudice and then choose the fresh frozen method and the fixed tissue method he can use most effectively from the standpoint of his training, experience and equipment.

It has always been a disadvantage for the pathologist to leave the operating room to cut the tissue and prepare the sections. In 1927 Bloodgood³⁹ developed and described a table with wheels equipped for carbon dioxide freezing sectioning and staining. It could be wheeled from one operating room to another. The advent of the dry-ice freezing stage for the microtome has greatly simplified and reduced the bulk and weight

39 Bloodgood (footnote 9 fifth reference)

of the necessary equipment. If to the freezing, sectioning and staining equipment a simple projection apparatus is added, the pathologist can readily do all his work in the operating room, and a microscopic section may be demonstrated to the entire operating team, thus adding to the knowledge of the case in hand, as well as teaching and stimulating interest in pathology.

THE RELATION OF BIOPSY TO TREATMENT

In spite of the perennial outcroppings of serum, chemical and endocrine, and other alleged cures for cancer, thorough surgical excision, radium or the roentgen rays singly or combined remain the only three weapons in cancer therapy that have stood the test of time and of accumulating accurate follow-up records. Their acceptance today is general and almost axiomatic, and much progress has been made in convincing the public and the medical profession of the advantages of their early use. It is not as generally recognized that the first attack on cancer not only should be early, but should be complete in kind and scope for the particular lesion. Nor is it recognized that in the estimation of such mass-attack treatment, biopsy information is of vital importance. The work of Broders,⁴⁰ Ewing⁴¹ and Regaud and Lacassagne⁴² tends to show that an adequate morphologic study of a tumor will indicate its histogenesis and degree of malignancy, including the metastasizing power and radiosensitivity. Hence this feature of the biopsy assumes an importance in our fight for better results in cancer therapy second only to that of educating the medical profession and the public to early and correct diagnosis.

CONCLUSION

A consideration of the interrelationships of the various aspects of the question of biopsy on which we have just dwelt indicates clearly the ideal conditions under which they may be obtained, namely, the tumor clinic, operating either as a separate hospital or perhaps better as a complete unit of a general hospital where surgeon, pathologist and radiologist, backed by optimum equipment and freed to some extent from encumbrances of other work, may cooperate to give patients by far their best chance of a cure. At present, owing to the prohibitive expense of complete equipment, these ideal conditions exist in so few places that they are available to a relatively small percentage of all patients with cancer.

Further consideration also suggests that there are distributed throughout this country enough hospitals with adequately trained pathologists, surgeons and radiologists sufficiently accessible by modern methods of transportation to offer to a high percentage of patients with cancer, quick biopsy, adequate surgical treatment and, for many, adequate irradiation treatment. Where such facilities exist there is little excuse for making use of a delayed biopsy.

There remain, however, far too many patients with cancer living where such facilities do not exist to disparage or condemn entirely the delayed biopsy. Its field of usefulness, however, is limited, and it should never be resorted to merely for the sake of establishing a diagnosis, i. e., never without some plan for treatment mapped out by the physician and accepted in

advance by the patient, should the diagnosis indicate a malignant condition.

SUMMARY

1 The worth of the biopsy in diagnosis, prognosis and as an index for treatment is at present thoroughly and soundly established.

2 Properly conducted, its lack of danger is likewise established. Its few contraindications are well known and recorded.

3 Its status as a technical procedure, though clearly allowing of future improvement, has attained a satisfactory level of combined simplicity in procedure and materials and of reliability in preparation.

4 Its opportunities for future development and practice under optimum conditions lie largely in stimulation of interest and furnishing of facilities for more pathologists and surgeons to devote the time and hard work necessary to perfect themselves in the difficult field of tumor pathology.

ABSTRACT OF DISCUSSION

DR WILLIAM CARPENTER MACCARTY, Rochester, Minn. Biopsy as an essential part of diagnosis has been a major principle in the Mayo Clinic for over a quarter of a century. It has four distinct functions: differential clinical diagnosis, research, prognosis and the direction of therapy. Since there are no reliable clinical or serologic tests for the recognition of early cancer and since cancer is frequently associated with chronic inflammatory conditions, experience has taught that biopsy is our only means of making differential diagnoses in many instances. In practice we have adopted the following rules: 1 Every chronic sore or lump recently acquired which does not disappear or become smaller or show signs of disappearance after two or three weeks of local noncorrosive treatment, rest, local antiseptic and general hygienic care should be subjected to biopsy. It should be excised if possible rather than incised. 2 The removal of tissue for biopsy should not be done unless the one who does it is capable of performing the radical operation in case malignancy is found or unless he is in close immediate proximity to some one capable of completing the operation. 3 The biopsy should not be performed, as a rule, on small doubtful lesions located near epiphyseal lines in children. There are, perhaps, rare exceptions to this rule. 4 Biopsy should not be undertaken if the immediate and ultimate operative risks are greater than the possibility of cancer. 5 Tissue may be removed by incision of the sore or lump if this is large and thought to be a hopeless condition with only a small chance of its not being malignant. Immediate radical operation should follow the diagnosis if past experience shows that radical operation will prolong useful life or make even a short life free from lingering suffering otherwise it is unnecessary. 6 Biopsy is often dependent on surgical exploration of body cavities in which some unrecognizable but incapacitating pathologic condition is known to exist. Differential clinical diagnosis in these systems is becoming more difficult and experience with surgical exploration shows that many small cancers are being found. In the hands of well trained operators, exploratory risks are relatively small. The conservative surgeon is apt to refrain from exploration unless the patient is at least partially incapacitated or unless roentgenologic studies show a definite lesion in one of the systems or unless there are no roentgenologic signs and the patient's incapacity is increasing despite ordinary non-surgical treatment.

DR MAX CUTLER, Chicago. It has been said that when a patient consults his physician for cancer the first move on the part of the physician determines the patient's fate. I subscribe to that and therefore believe that the question of biopsy occupies a predominant place in the entire scheme of cancer diagnosis and treatment. It is for that reason that I particularly welcome the detailed and elaborate preparation and thought that Dr McGraw and Dr Hartman gave to this subject. The presentation of this subject has been so comprehensive that it is exceedingly difficult to add anything to it. I would emphasize several practical points in relation to biopsy. When the lesion

is very small (0.5 or 1 cm in diameter) the question arises as to whether it may not be best to remove the entire lesion rather than incise it. Under this circumstance the diagnostic and therapeutic measures are combined in one procedure. When the lesion is very small clinically and one has observed a sufficient number of them, one can often predict with considerable accuracy that microscopically there will be found a so-called borderline structure. Those who possess sufficient clinical experience and adequate familiarity with the pathology of tumors may treat such a lesion with biopsy if irradiation is to be used. That, I think, represents one possible exception to the general rule of performing biopsies. Thus the possible danger of biopsy may be avoided. When a breast tumor is large, the error is frequently made of performing an inadequate local excision of the tumor under the false impression that the mass is being excised widely. I should like to ask the authors whether they do not think that under those circumstances a very careful incision into the tumor, as Dr Halstead formerly practiced, phenolizing the wound and changing the instruments, is not safer than the unsuccessful attempt to remove a large tumor widely for diagnosis. Finally, there is the question of exploratory biopsy, if one may call it that. A patient I saw had a large tumor of the thigh. The clinical impression was that the lesion was a fibrosarcoma. I hesitated whether to incise over that region because of the possibility of disturbing the capsule. I decided to perform a biopsy, with the result that when the fascia was incised it proved to be a deep-seated lipoma. Thus the true diagnosis is sometimes established by gross examination after exploratory incision.

THE AUTOPSY PROBLEM

ITS SOLUTION IN SMALLER COMMUNITIES

GEORGE W. COVEY, MD

LINCOLN, NEB

Medical schools of the better class are usually, though not invariably, located in large communities and here the study of medicine tends to be centered. The examination of the dead is an important part of this study, hence one finds the autopsy work largely concentrated in these centers. Conversely, most of the smaller communities have no medical schools nor any direct connection with them. Furthermore, the patients are for the most part private, pay, patients, the family doctor is more or less intimate with the members of his community, he is not stimulated by a great teaching institution and the research spirit it engenders, he may even shrink from exposing the mistakes which he and all of us make. These things tend to make the autopsy the unusual rather than the routine procedure in these communities.

Even the large standardized hospital frequently has difficulty in obtaining permission for the postmortem examination of the required 15 per cent of its deaths and many of them are able to do so only because of the constant pressure on them by the American Medical Association and the threat of losing the name of 'class A hospital.'

In smaller hospitals, in smaller communities without the proper support of their staffs and often without or with only a part time and perhaps insufficiently trained pathologist, the problem is still greater. The need of educating the profession to want and demand autopsies and of educating the public to understand the benefits to be derived from this service is the greater, the smaller the community.

Davidsohn¹ has recently pointed out some significant facts in regard to the number of autopsies performed

that the number has been markedly increased in a certain class of hospitals apparently as a result of the drive for standardization by the American Medical Association, that regardless of this increase probably less than 2 per cent of all dead are examined post mortem, that therefore 98 per cent of vital statistics are totally or highly unreliable.

He expresses the opinion that the movement is doomed to failure or a very mediocre success as long as the whole load is shouldered by the medical profession and believes that real success is dependent on making the public view this work as a public health problem. This, of course, means laws compelling submission to autopsy the same as they now do to quarantine and other preventive measures in public health. He further points out the necessity of education beginning in the ranks of the medical profession.

With these facts in mind I am going to describe the methods used in Lincoln, Neb., and set forth the results obtained. I hope these methods and results may encourage other groups of physicians to greater effort in obtaining autopsies and perhaps suggest a plan whereby this larger number may be done with the least cost and the greatest benefit to the physician, the hospital and the public we serve.

Our problems in Lincoln were much the same as in smaller cities with no medical school connections. For years there was only an occasional postmortem examination. These were done by individuals relatively untrained in pathology. There was inadequate examination of the bodies and very poor and incomplete histologic study. The information obtained was seldom correlated with the clinical aspects of the case and, if so, it was not a staff function in our hospitals.

With the addition of new hospitals and the determined efforts at standardization, part time pathologists were added to the staffs and conditions improved somewhat. This improvement was, however, largely in the number of autopsies performed. Standard methods of performing the examinations, adequate records, thorough histologic examinations of the tissues, preservation of museum specimens and, perhaps as important as any or all of these, the correlation of clinical and pathologic observations as a staff function, were not carried out or were done very poorly.

Under these conditions, not only were relatives of the deceased difficult to convince of the need, but the majority of the physicians were only tolerant or totally uninterested in obtaining autopsy permission.

Another very important factor was the mortician. With varied personnel performing autopsies, using a medley of methods, and often scornful of the rights of the embalmer, there was constant discord. It came to be almost axiomatic that unless permission was obtained and an autopsy started before the family and mortician could consult about the matter, there could be no autopsy.

Realizing these facts, the three Lincoln hospitals, Saint Elizabeth's, Bryan Memorial and the Lincoln General, united in a definite plan as follows. Each hospital contributed the sum of \$50 a month to a common fund. With this fund a central laboratory, known as the Hospital Laboratory, was set up and maintained in the Lancaster County Medical Society quarters in conjunction with a museum and medical library. A full time technician was employed with the addition of a part time stenographer.

The technician's duties have included the routine care and preparation of tissue for microscopic study, taking

¹ Davidsohn, Israel. *The Autopsy*. An Outline of the Problem. *Am. J. Clin. Path.* 3: 199 (Mar.) 1933.

of notes as dictated at the autopsy, a part of the other stenographic work, the filing and indexing of museum materials, and the preservation of museum specimens, though further work on these, such as mounting, is done by others.

Autopsy teams consisting of the autopsy surgeon and an assistant were gradually developed. At first there was one so-called team. In time the assistant became a number one man and another assistant was added for each autopsy surgeon until, at the end of nearly five years, seven such teams are carrying on this work. Interns from the hospitals are also used as assistants as often as possible. I think that the criticism now being made that these are relatively untrained pathologists is a point well taken. However, full time pathologists were not available nor could they be paid. All the men who have entered this work were previously trained in some degree, were highly interested in this kind of work and, of still greater significance, were willing to follow an established routine and study the job. They have all worked without other remuneration than the knowledge to be obtained and the expression of their loyalty to their respective institutions.

These autopsy teams have constantly worked toward standard and uniform methods of doing and recording the results of the examinations. The records are all read and corrected to conform to the adopted standard by the one who has charge of this work. After correction three copies are typed, one of which is filed in the museum, another returned to the hospital and the third given to the attending physician. The work is not limited to the hospitals but any physician in the Lancaster County Medical Society may ask these teams to do his autopsies. It is interesting in this connection that approximately one third of the autopsies done by this setup have been outside cases, that is, cases not having been in one of the hospitals.

The examination of the microscopic sections has been done largely by one man. During the last year, however, two other men have gradually taken over a part of this work, so that in the coming year it will be about equally divided among the three. All sections are filed in the museum and indexed. A system of cross indexing of tissues has not been carried out because of lack of help and funds, though this will be done in time.

I want to return at this point to the situation regarding our relations with the morticians. We gradually made friends with them by making concessions. One by one they were convinced that we desired to work with them rather than against them and that to this end we would make certain concessions if they would. We agreed that the undertaker should inject the circulation before the autopsy, and in return he abstained from using a trocar in the cavities and the heart. In addition, most of them tried various embalming fluids to find the one that left the tissues most nearly natural in color and consistency. There are embalming fluids that cause practically no change in these characteristics and that do not damage the tissues from the standpoint of histology. They are no more difficult to use but are somewhat more expensive.

Furthermore, we have tried always to avoid so far as possible any unnecessary mutilation or the production of marks that cannot be covered in preparing the corpse for the inspection of friends and relatives. As a result of these things the morticians are now of the greatest help to us. They often obtain autopsy permissions that we have been unable to get, in fact, they

have obtained permission in cases in which no permission has been asked.

The depression has caused us some trouble and a good deal of anxiety. In April, 1932, Saint Elizabeth's Hospital had to withdraw its support and we were soon informed that the other two would do likewise, though the Bryan Memorial continued until June 1 and the Lincoln General until Sept. 1, 1932. In order to avoid losing the results so far obtained, a number of physicians immediately agreed to donate from their private funds enough money to maintain the laboratory and pay the technician half time, and the laboratory proposed to the hospitals that we continue to do their work just as we had, so far as possible, until such time as they could again contribute to its support. This was accepted by all but one hospital. This one has carried on its own work since April 27, 1932. With the others there has been no break in continuity. I am detailing this because of its effect on the statistics about to be given.

During the four years and five months from Feb. 1, 1929, to May 31, 1933, this central laboratory has performed 599 autopsies. The one hospital that preferred to carry on independently for the present has performed an additional 58 from April 27, 1932, to May 31, 1933. This is a total of 657. During this period there were 3,971 deaths in the city of Lincoln. Therefore, autopsies were done in 15.5 per cent of all these deaths.

Of the 657 autopsies performed, 480 were from the three hospitals. During this period 1,438 patients died in these hospitals. Therefore, autopsies were done in 33.4 per cent of these deaths. The proportion of autopsies at each of the hospitals for the whole period is as follows: at St. Elizabeth's, 28.1 per cent, at the Lincoln General, 30.7 per cent, and at the Bryan Memorial, 49.1 per cent. The proportion of autopsies on all other deaths in Lincoln for this period is 7 per cent.

In addition to the data accumulated in this manner and filed and indexed for the use of any member of the county medical society, much of it is studied very thoroughly and used in clinicopathologic staff conferences at the various hospitals. For example, during 1932-1933, sixteen such conferences were held at which thirty-two cases were presented in detail both clinically and from the standpoint of pathology. These conferences are among the best attended medical meetings we have, bearing evidence of the present interest of the doctors in our community in the autopsy as a teaching possibility. Further evidences of the interest they have developed as the result of this scheme of carrying on the work are the effort put forth to obtain autopsy permission and the generosity of the physicians as a whole in helping sustain the laboratory financially during the depression.

SUMMARY

Lincoln, a moderate sized city, without a medical school, has by the method outlined developed such interest in autopsies that over a period of fifty-three months we have done 657 autopsies with complete records, examined and recorded the histopathologic observations, and properly correlated the clinical and pathologic observations in a large number of them as a staff function of our hospitals. This constitutes an autopsy percentage of 15.5 on all deaths in the city for this period, which is over eight times the general average in the United States and 33.4 per cent for all deaths in the three hospitals for the same period, or

well over twice the percentage required for standardization

CONCLUSIONS

- 1 There is great need of increasing the number of well done and well studied autopsies, especially in the smaller communities
 - 2 To do this the medical profession must be made autopsy conscious and the autopsy must be made interesting and profitable to the physician
 - 3 The cooperation of the mortician is necessary, it can be had and it is invaluable
 - 4 A plan such as the one adopted in Lincoln is workable and could be adapted to almost any community
- Sharp Building

CANCER-LIKE LESIONS OF THE UTERINE CERVIX

RICHARD W TELINDE MD
BALTIMORE

Every year in the Gynecological Pathology Laboratory of the Johns Hopkins Hospital a few histologic lesions of the cervix are encountered which in certain respects suggest carcinoma and which at times evoke differences of opinion among the staff members as to their benign or malignant nature. Judging from the interesting "suspicious" sections sent to the laboratory from other clinics, it is obvious that others are encountering the same difficulties. The easiest course to follow in a case of uncertain histologic diagnosis is to appease one's scientific conscience with the thought

vinced that hundreds are sacrificed annually which might be saved if pathologists generally were more familiar with the finer nonmalignant changes in the cervix as well as the earliest histologic signs of malignancy. When one appreciates the fact that panhysterectomy and the bilateral salpingo-oophorectomy which usually accompanies it, when done for malignancy, is

Fig 2—Portion of cervical polyp showing marked epidermization. The epithelial strands lie deep within the stroma of the polyp the surface of which is covered with columnar and atypical squamous epithelium.

Fig 1—Curettings showing plaques of stratified squamous epithelium obtained from the cervix. This was erroneously considered carcinoma.

that if the lesion is not cancerous it may be "precancerous" and should therefore be removed. As a result of this method of reasoning I have examined several uteri that had been removed unnecessarily and am con-

vinced that hundreds are sacrificed annually which might be saved if pathologists generally were more familiar with the finer nonmalignant changes in the cervix as well as the earliest histologic signs of malignancy. When one appreciates the fact that panhysterectomy and the bilateral salpingo-oophorectomy which usually accompanies it, when done for malignancy, is

an operation which carries with it a definite mortality and morbidity, it is apparent that womankind is suffering because of the profession's incomplete knowledge. The same may be said of the unnecessary use of radium, which at times carries with it a morbidity which should not be lost sight of when advising its use. At this point it may be advisable to scrutinize the meaning of the much abused word "precancerous." On reviewing the literature, one is struck by the loose manner in which this word is used. Gynecologists refer to lesions as "precancerous" when they have no further evidence of their precancerous nature than the fact that they somewhat resemble cancer histologically. How, then, should the term "precancerous" be employed? If a certain lesion invariably becomes cancerous, if unmo- lested, it must be considered as representing an early stage of actual cancer, even though histologically the significant cell changes in that stage may as yet be unrecognizable. For a lesion to be considered "pre- cancerous" it must be established that the incidence of carcinoma developing in such cases is greater than that of carcinoma in persons free from such a lesion. As an example of a lesion now definitely recognized as precancerous one might cite leukoplakia of the vulva. Taussig showed that carcinoma of the vulva was pre- ceded by leukoplakia in over 50 per cent of the cases in his series. This clinical association of the disease is further substantiated by Smith and Graves, who found on examination of twenty-one specimens of vulval carcinoma that sixteen also showed leukoplakic

changes. To a lesser degree, cervical lacerations with the resultant chronic cervicitis may, in a sense, be considered precancerous, as is shown by the high percentage of parous women among victims of this disease (Graves, 90 per cent, Cullen,¹ 98 per cent, Sampson, 97 per cent). There is also clinical evidence to show that eradication of cervical infections decreases the

Fig 3—High power magnification of deep lying strands of epithelium. The cells are uniform in type except as they become flatter and concentrically arranged near the center of each strand, forming pearl like patterns. No mitoses are present.

incidence of carcinoma. For example, Smith and Pemberton² state that in their series of 1,408 cervical cauterizations none of the patients were known to have developed cervical cancer. It is thus obvious that there is clinical evidence that inflammatory lesions of the cervix predispose that organ slightly to carcinoma, and in that sense they may be considered precancerous. It is, however, one thing to recognize this clinical fact and quite another to establish a histogenetic relation between certain inflammatory lesions of the cervix and carcinoma.

A review of the literature reveals many reports of cancer-like lesions of the cervix. Among others, the report of Stone³ is noteworthy. This shows excellent photomicrographs of lesions designated as "precancerous." On studying the text, however, one finds that no evidence is presented to prove that any of these lesions subsequently became carcinoma. Novak⁴ has called attention to cancer-like lesions which he considers benign. He states, however, "As we have not as yet made a follow-up analysis of our cases from this standpoint, I can for the present give only impressions rather than actual facts."

As has been repeatedly emphasized by Meyer,⁵ the question of whether a lesion is malignant or benign can be determined only by the patient's subsequent clinical course. There can be no controversy over this point of view. In the present series my associates and I have followed the cases clinically and feel that the results are of value in determining whether or not any of these cancer-like lesions subsequently developed into actual cancer and whether the term precancerous may properly be applied to them. Ewing has said, "It is not true that a pathological condition must be either cancer or not cancer. It may be neither one nor the other. It may be in the process of becoming cancer." One must admit the truth of this statement on theoretical grounds, but, as practical gynecologists, we wish to know whether or not a histologic picture of the cervix can be recognized which represents a transition from the nonmalignant to the malignant or whether a lesion exists which under certain conditions may become malignant. The importance of biopsy in suspicious lesions of the cervix has been emphasized by Meyer, Kaufmann,⁶ Hirshberg, Cullen, Novak and others. Hinselman, by the use of his colposcope, has enlarged the field of biopsy by uncovering many leukoplakic lesions suggesting malignancy which would escape the unaided eye. In view of this increasing trend to employ biopsy in doubtful lesions, the gynecologic pathologist is called on more and more for a differential diagnosis in the very early pathologic changes. To do this, he

Fig 4—Epidermization of surface epithelium penetrating deeply into the stroma of the cervix.

must be familiar with all lesions of the cervix, inflammatory, cancerous, cancer-like, and precancerous, if such a lesion as the last named is recognizable.

The material on which this study is based is derived from histologic lesions encountered in the routine

examination of cervical tissue coming to the laboratory. The microscopically suspicious lesions were found in twelve instances in cervical polyps which were simply twisted off, no attempt being made to remove the tissue radically about the base of the polyp. The lesions were accidentally found in tissue removed at trachelorrhaphy in three and at amputation of the cervix in one case.

Fig 5—Marked epidermization of surface epithelium in cervical canal which invades the stroma deeply. The individual cells show no evidence of malignancy.

Results of Operations

Case	Operation	Result	Time Elapsing
1	Removal of cervical polyp	Well	2 yrs
2	Panhysterectomy, resection of cyst of right ovary, appendectomy	Well	1 yr 6 mos
3	Dilation and curettage, removal of cervical polyp	Died of hemiplegia	3 yrs
4	Vaginal panhysterectomy	Well	2 yrs 6 mos
5	Removal of cervical polyp	Well	3 yrs
6	Trachelorrhaphy, perineal repair	Well	4 yrs
7	Removal of cervical polyp	Well	2 yrs
8	Removal of cervical polyp	Well	4 yrs 3 mos
9	Removal of cervical polyp	Well	1 yr 6 mos
10	Panhysterectomy, double salpingo oophorectomy	Well	4 yrs
11	Removal of cervical polyp	Well	3 yrs
12	Removal of cervical polyp	Well	1 yr
13	Vaginal panhysterectomy, posterior colporrhaphy	Well	1 yr 9 mos
14	Biopsy (cervix)	Well	1 yr
15	Trachelorrhaphy, dilation and curettage	Well	1 yr
16	Panhysterectomy, left salpingo oophorectomy	Well	3 yrs

attempt to find unmistakable cancer in the same cervix, with the idea, particularly, of tracing continuity between the cancer-like lesions and true cancer. In none of the instances was definite microscopic cancer encountered. In this way we have attempted not only to check up our histologic diagnoses but also to learn the true significance of questionable cervical lesions. The patients were followed for from one to ten years. The accompanying table shows the results of these investigations.

It is obvious from the examination of the table that there is no evidence that any of these patients subsequently developed carcinoma of the cervix. In the cases in which polyps were removed or in which tissue was removed for biopsy or by trachelorrhaphy, the theoretical objection might be raised that these simple procedures removed the "precancerous" tissue and hence one would not expect a subsequent development of carcinoma. That this objection is not valid, however, is shown by the fact that these changes, when present in the cervixes removed by panhysterectomy, were not usually localized at one point but could often be demonstrated at several points in the same cervix. It is therefore not likely that the simple procedure of biopsy, trachelorrhaphy or removal of a cervical polyp would have taken away all of the tissue showing this change. In spite of this, none of these patients developed cervical cancer. Two died three and seven years, respectively, after the original operative procedure, but neither had shown symptoms of carcinoma. In the cases in which panhysterectomy was done, careful study of many sections failed to show undoubted carcinoma at any portion of the cervix. In specimen 23, sent to us from another laboratory, an erroneous diagnosis of carcinoma was made from the microscopic picture shown in figure 1. The plaques of stratified squamous epithelium, obviously removed from the cervix in performing the curettage, were taken as indicative of

Fig 6—Isolated plaques of squamous epithelium buried deeply beneath the surface but high power magnification showing the individual cells to appear benign in character. There is marked round-cell infiltration.

malignancy, and a panhysterectomy was performed. Careful subsequent examination of the cervix failed to show evidences of carcinoma. The examination of the endometrium in the original curetting showed marked benign endometrial hyperplasia, which undoubtedly explained the symptom of bleeding.

I shall consider in some detail the histologic pictures presented by the cases followed in this series. The car-

In one instance the tissue was removed for biopsy of a suspicious cervical lesion and in one instance by curettage. In six cases the routine examination of cervixes removed by panhysterectomy showed cancer-like lesions. From all such cases several blocks were cut and several sections studied from each block in an

cinoma-like picture may suggest epidermoid carcinoma or adenocarcinoma. The first variety is more frequently encountered. Figure 2 shows, under low magnification, a portion of a cervical polyp in which epithelium of the squamous type has gone far into the stroma. A

Fig. 7—Glandular lumen almost obliterated by the proliferation of epithelial cells of the squamous type

large portion of the surface of this polyp is covered with columnar cervical epithelium with scattered areas of so-called epidermization, that is, a replacement of cylindric epithelium by the squamous type. In places,

Fig. 8—Marked proliferation of squamous epithelium in the cervical glands pushing before it the columnar layer of cells which is preserved intact

a gradual transition of the columnar into the squamous type seems to be present. Under this magnification the picture is strongly suggestive of malignancy. Solid strands of cells lie deep in the stroma and in places these are apparently isolated from the surface epithelium. The general pattern of the growth is extremely

irregular, resembles no normal pattern, and suggests malignancy. Careful examination under higher magnification, however, is necessary to a final decision on this point. Figure 3 shows this deep-lying epithelium under sufficient magnification to observe the character of the individual cells. These are seen to be relatively uniform as to size, shape and staining qualities, except for a tendency to hornification toward the center of the individual strands forming pearl-like structures. A typical basal layer of cells, more or less columnar in type, such as is seen in normal cervical mucosa, is for the most part lacking. Scattered through the epithelium are several pyknotic nuclei, but large hyperchromatic nuclei as well as mitotic figures are not found. Hence under magnification sufficient to study the character of the individual cell one finds it difficult to consider this lesion malignant in spite of the first impression gained by inspection under low magnification. Its benign nature is confirmed by the fact that the patient has remained well for two years after the simple twisting off of the polyp.

Lesser degrees of similar benign invasion of the cervical stroma can be seen in figures 4 and 5. In figure 6, several apparently isolated strands of squamous epithelium are seen lying deep in the cervical stroma, but

Fig. 9—The adenomatous pattern formed by squamous metaplasia of cells lining the glands. This pattern is sometimes erroneously considered adenocarcinoma

under higher magnification these, too, show no cellular changes suggesting malignancy. On serial section several of these "isolated" epithelial areas can be seen to be continuous with the surface epithelium. The failure to establish continuity, however, by no means indicates malignancy, for inflammation and the resultant fibrosis may isolate strands of benign epithelium from the parent surface layer. Figure 6 shows a marked infiltration with round cells, indicating inflammation, the invariable accompaniment of the irregular epithelial proliferation. The downgrowth of squamous epithelium frequently follows a glandular lumen and many fill the entire passage with a solid cord of epithelium. Figure 7 shows such a process in which the lumen is partially obliterated. Often this epithelial proliferation takes place beneath the columnar epithelium of the gland, preserving the latter as the most superficial layer. This is shown particularly well in figure 8.

Another histologic lesion giving rise to confusion is an adenomatous picture somewhat suggestive of adenocarcinoma. Figure 9 shows such an instance under low magnification. Often this picture is seen deep

beneath the surface epithelium, which further suggests malignancy. Under higher magnification the process may be recognized as simply another form of essentially the same process of the epidermization described. The normal columnar epithelium lining cervical glands has been replaced by epithelium resembling the squamous type. The glandlike spaces of this adenomatous picture are in part actually gland lumens of cervical glands partially obliterated by the growth of epithelium. Other smaller lumens are simply the result of cellular degeneration. The lumens are often filled with cellular debris. Figure 10 shows such an adenomatous picture under higher magnification. Careful examination of the individual cells fails to reveal hyperchromatic nuclei or mitoses.

In the vast majority of cases these "cancer-like" benign histologic lesions are readily differentiated from early carcinoma, provided the pathologist is cognizant of their existence. In some, however, in which this epidermization is extreme, difficulty may be encountered

Fig 10—Higher magnification of adenomatous pattern showing proliferation of lining epithelium to two or three layers deep. In places solid strands of epithelium of the squamous type have been formed.

in arriving at a correct diagnosis. Early carcinoma may often travel into the depths of the cervix by way of glands in much the same way as benign squamous epithelium. Figure 11 shows such an invasion in a very early carcinoma accidentally discovered in a routine examination of a cervix removed because of lacerations and infection. At times a suspicion of malignancy will be aroused by the manner of invasion, which shows actual destruction of the columnar epithelium of the gland instead of a simple proliferation beneath retained columnar epithelium so frequently present in benign epidermization. When invasion of malignant epithelium is marked there is no difficulty in recognizing it as cancerous but in the earliest cases there may be nothing particularly characteristic about the malignant invasion to contrast it with a benign downgrowth of epithelium. So in the doubtful cases the decision frequently rests on a careful examination of the individual cells under high magnification. The

diagnosis of malignancy in the case shown in figure 11 must be made entirely on this basis.

Deviation from the normal as shown by irregularities in size, shape and staining qualities are all points in

Fig 11—Section from a very early carcinoma accidentally discovered in a cervix removed for chronic infection with fibroids. The pattern of the invasion differs in no way from that of the benign conditions pictured here. The diagnosis of malignancy is made entirely on the character of the individual cell changes.

Fig 12—High power magnification of small area from figure 10. The mitotic figures and hyperchromatic nuclei definitely establish the diagnosis of malignancy.

favor of malignancy. A retention of the normal differentiation of cells in squamous epithelium into the basal, transitional and spinal layers is a point against

malignancy. Its absence, however, does not necessarily indicate malignancy, for in the squamous epithelium formed by the process of epidermization this differentiation is often wanting. Hyperchromatic nuclei are suggestive of malignancy, and mitotic figures in the cervical epithelium are of great significance. The finding of both establishes a diagnosis of malignancy. Figure 12, which represents a small area of figure 11 under higher magnification, shows both mitotic figures

Fig. 13—The transition between columnar and squamous epithelium on the surface of an infected submucous fibroid which had its origin high up in the uterine cavity

and hyperchromatism. Such a picture would signify malignancy even if found in the surface epithelium entirely without evidence of invasion.

The presence of mitoses in various tissues of the body is of variable significance as regards malignancy. For example, mitoses are frequently seen in the epithelium and stroma of the endometrium in the postmenstrual stage. They are also encountered in benign hyperplasia of the endometrium. In none of the lesions studied in this series were mitoses found, in spite of a careful search. In discussing Martzloff's⁷ reported case of early carcinoma of the cervix, Cullen says: "We fully realize that nuclear figures do occur in the squamous epithelium, otherwise there could be no reparation when defects occur. But they are so uncommon that we have not encountered them in our routine work except where malignancy exists. We have also failed to note them in cylindrical epithelium of the cervix." H. R. Schmidt,⁸ however, has definitely demonstrated mitotic figures in regenerating cervical epithelium. He destroyed the cervical epithelium by cauterization, amputated the cervix six, eight, ten and twelve days afterward, and made microscopic studies of the tissue thus removed. Mitoses were frequent in the regenerating epithelium. Notwithstanding this experimental fact, experience has taught that they are extremely rare except in malignant cervical epithelium. A diagnosis of malignancy cannot be made on finding a single mitotic figure, but the identification of even one should call for a careful search, which will usually reveal several as well as other changes indicating malignancy.⁹

⁷ Martzloff, K. H. Bull. Johns Hopkins Hosp. 33: 221 (June) 1922. 40: 160 (March) 1927.

⁸ Schmidt, H. R. Ztschr. f. Geburtsh. u. Gynak. 90: 48, 1926.

⁹ Since the completion of this study I have examined a biopsy section of a cervix which resembled the lesions of this series except that an occasional mitotic figure was present. The cells otherwise showed no changes suggestive of malignancy. The case will be followed with much interest but as no appreciable time has elapsed since the biopsy the exact status of this case cannot be evaluated.

As to the etiology of these "carcinoma-like" microscopic pictures, there can be little doubt that inflammation is the essential factor in their production. We have never seen such a microscopic picture except in the presence of demonstrable infection. The same process of epidermization may occur in the mucosa of the body of the uterus, but always in the presence of infection. Figure 13 shows such a process in the endometrial surface covering an infected submucous fibroid. Rarely, the entire uterine cavity may become lined with squamous epithelium in the presence of severe chronic infection, particularly in elderly women. Figure 14 is a section of endometrium showing such extreme epidermization high up in the uterine cavity. The squamous epithelium may be of unusual thickness and penetrate deeply into the endometrial stroma. Cross sections of the penetrating processes may show pearl-like structures.

Concerning the origin of this squamous epithelium which replaces the columnar either in the cervix or in the endometrium, three possibilities may be considered:

1. The growth by direct extension of squamous epithelium from its normal habitat, replacing the columnar epithelium of the cervix or endometrium following the destruction of the latter by inflammation.

2. Transformation or "metaplasia" of adult columnar epithelium into epithelium of the squamous type.

3. The growth of squamous epithelium from embryonal rests of epithelial cells that have retained a potential power to develop into epithelium of the squamous type under the proper stimulus.

As in many pathologic lesions, a better concept of the origin may be obtained from early lesions rather than from those that are fully developed. Figure 15 shows small early lesions in which squamous-like patches are developing in the lumen of a cervical gland. The finding of such isolated patches of squamous epi-

Fig. 14—Surface of endometrium in which the columnar epithelium is entirely replaced by heavy stratified squamous epithelium. This epithelium in the presence of marked endometritis penetrates deeply into the endometrial stroma. The individual epithelial cells show no changes suggesting malignancy.

thelium apparently blending with the columnar type suggests a direct metaplasia of one type into the other, but Meyer would explain such a picture on the basis of the development of the squamous epithelium from an epithelial rest retaining the potential capability of developing into epithelium of the squamous type on the incitation of some stimulus such as inflammation.

These more or less theoretical considerations as to the origin of these microscopic pictures are interesting but possibly cannot be definitely proved. In mentioning them it is not my purpose to detract from the main clinicopathologic theme of this paper. It has been my purpose to call the attention of pathologists and surgeons to these histologic pictures which are at times confused with carcinoma and to remind them that, although the pictures are cancer-like, there is no real evidence that they are precancerous. It has further been my purpose to show that there is no justification for radical surgery solely on the basis of these microscopic lesions. When doubt exists after examination of biopsy specimens by competent pathologists, such

Fig 15—Glandular lumen showing three areas in which small plaques of squamous epithelium blend with the normal columnar epithelium lining of the gland. Areas such as this suggest a metaplasia of the columnar to the squamous type.

patients should be kept under the closest observation and a second biopsy instituted if necessary. It is only by carefully following such patients that the true significance of questionable lesions of the uterine cervix can eventually be learned. Further, it must be admitted that with present knowledge there is as yet no microscopic picture from the cervix which can justifiably be interpreted as a transition between the benign and the malignant.

1107 St Paul Street

ABSTRACT OF DISCUSSION

DR. GEORGE H. GARDNER, Chicago: Dr. TeLinde has rendered a real service by directing attention to the histologic picture of cancer-like lesions of the cervix. He has presented clinical and laboratory proof that such conditions are benign; that they are not precancerous; and that patients harboring such lesions should not be subjected to radical surgical procedures or to heroic doses of radium. I wish that Dr. TeLinde had told more about the complaints which his patients presented of the observations and of the gross appearance of the lesions in the operating room. It would be interesting to know the results of the Schiller test and the colposcopic examination in these

patients. Such additions to the microscopic data would have made the picture complete. I hope that he will report them in a subsequent paper. From the standpoint of practical gynecology, a given lesion of the cervix must be considered either benign or malignant. It is not yet possible to recognize those features which denote that a benign lesion is passing over into a malignant cervical growth. Such a metamorphosis cannot be identified either grossly or in histologic preparations. After careful consideration of the patient's history and thorough, painstaking examination of the cervix under ideal conditions of relaxation, exposure and illumination one can almost invariably make a clinical diagnosis of cancer. The pathologist must be looked on as an invaluable consultant, not as a prophet. When he is confronted with a difficult microscopic picture, such as Dr. TeLinde has just shown, he should not be required to give an unqualified opinion based solely on the information which he can derive from one or two sections. The final diagnosis is more wisely made after a thorough review of all available information, history, physical examination and gross characteristics of the lesion, as well as its microscopic appearance. When competent gynecologic histopathologists disagree on the benignancy or the malignancy of a given section of the cervix, it can be concluded, with considerable assurance, that the growth is benign.

DR. RICHARD W. TELINDE, Baltimore: The reason the Schiller test and colposcopic examinations were not done in these cases was that the tissue in most of the cases was removed before colposcopic examinations and the Schiller test were in general use. At the present time careful histologic examinations together with follow-up studies should be done on a series of lesions found to be suggestive on colposcopic examination and with the Schiller test.

BENIGN LESIONS OF THE FEMALE BREAST SIMULATING CANCER

MAX CUTLER, MD

Director, Tumor Clinic, Michael Reese Hospital
CHICAGO

Authorities on the subject of neoplasms of the breast are agreed that radical excision constitutes the accepted method for the treatment of all tumors of the breast which exhibit the clinical signs of cancer. This attitude has brought into prominence a group of innocent lesions of the breast accompanied by such classic signs of cancer as to lead to their radical removal under erroneous diagnoses. As the education of the laity has progressed and patients consult their physicians more often soon after the first signs of disease, the task and responsibility of the physician have been greatly increased both in diagnosis and in treatment.

It is the purpose of this communication to describe several innocent states of the breast which simulate cancer and discuss the diagnosis and treatment of some borderline conditions the exact nature and future course of which it is becoming increasingly difficult to estimate as they are encountered in their earlier stages.

PLASMA CELL MASTITIS

The term "plasma cell mastitis" has been applied by Ewing to an acute and subacute inflammatory state of the breast in which a rich plasma cell exudate often forms a striking microscopic feature. Ewing¹ was the first to call attention to the gross and microscopic features of this condition in the laboratories of the Memorial Hospital. These laboratory observations

Read before the Section on Pathology and Physiology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

¹ Ewing cited by Adair, F. E. Plasma Cell Mastitis—A Lesion Simulating Mammary Carcinoma. Arch. Surg. 26: 733 (May) 1933.

were followed by clinical studies by Adair² and myself, and these observations have been recorded in the literature. In a careful analysis of ten cases observed in the Memorial Hospital Adair has directed attention to the various phases of this disease.

I have reviewed the older literature and have failed to find reference to acute or subacute inflammation of the nonlactating breast with the exception of that complicating acute general infections such as typhoid fever and parotitis.

That the clinical features of this condition may have been noted previously is indicated by an isolated observation in which Courtin³ in 1899 presented before the Bordeaux Medical and Surgical Society a case of subacute mastitis simulating a malignant tumor of the breast. The patient was 50 years of age, and the menopause had occurred four years previously. The tumor had been present three months and possessed many of the classic features of cancer. It was firm and fixed to the skin. The nipple was retracted, and the axillary lymphatic glands were enlarged. The tumor was, however, exquisitely tender, and the skin was reddened and warm. The lesion was treated by means of local applications. After four weeks there was no evidence of disease, the tumor having completely disappeared. In the discussion of this case, Coquet referred to a similar observation. Neither of these clinical observations is supported by microscopic evidence.

In 1932 Cohn and Bloodgood⁴ reported a series of cases of nonsuppurative chronic lactation mastitis, some of recent origin, others appearing months or years after pregnancy. Microscopic study of the sections showed evidence of residual lactation in all the cases. I have recently observed a case of plasma cell mastitis in a woman aged 40, in whom there had been no previous pregnancies.

CLINICAL FEATURES

A breast which is not the seat of lactation may become acutely inflamed, and in its earliest stages the condition gives rise to a clinical picture simulating inflammatory carcinoma. The disease begins suddenly and is ushered in with pain, diffuse tenderness and redness of the skin. The entire breast becomes swollen, and the axillary lymphatic glands are enlarged and tender. There is usually some rise in temperature, sometimes accompanied by a chill. A creamy discharge from the nipple is occasionally noted. The most important differential point from inflammatory carcinoma is the absence of a dermal and subdermal thickening representing invasion of these sites by tumor cells.

The acute symptoms soon begin to subside, and the process enters a subacute stage, during which period the symptoms and signs mentioned are present in a diminishing degree and begin to disappear. As the inflammatory signs disappear and the swelling of the breast diminishes, there remains a mass in the breast which often presents many or all the classic clinical signs of cancer. The mass is solid firm and often adherent to the overlying skin, which is dimpled and the nipple is sometimes retracted. These clinical signs, accompanied by enlarged axillary lymphatic glands, justify a diagnosis of carcinoma. Actually, until this

syndrome became fully recognized, this error in clinical diagnosis occurred in every case that came to the attention of my associates and myself.

An interesting though confusing peculiarity of this disease is the slowness with which the tumor mass regresses. In several examples in which the patients were examined carefully at weekly intervals, it was discovered that a detectable regression could be determined only after intervals of from three to four weeks. The change, though definite, was so slow as to revive the suspicion that carcinoma was present. During this prolonged observation it is important to establish with certainty that the mass is diminishing in size as this is the crucial sign which enables it to be differentiated from carcinoma in this stage of the disease. The following case, which I had an opportunity to observe closely from the onset of the disease, is a typical example of this condition.

REPORT OF CASE

The patient was a woman aged 50. The last pregnancy had occurred twelve years previously. The patient had sudden pain and tenderness accompanied by redness and swelling of the right breast. The temperature was 100.2 F by mouth. The entire right breast was edematous and exquisitely tender. The overlying skin was red. In the central portion of the right breast was an indistinct, firm mass. The axillary lymphatic glands were enlarged and tender. As an abscess was suspected an aspirating needle was inserted into the center of the mass, and several drops of purulent-looking material were withdrawn. On microscopic examination, this material showed leukocytes and epithelial debris. The signs of acute inflammation disappeared after one week. As the edema of the entire breast subsided the mass in the central portion of the gland became more discrete. It measured about 6 cm in diameter. Examination at weekly intervals showed that the mass was diminishing in size. The regression was, however, so slow that eight weeks after the onset of the disease there still remained a mass 3 cm in diameter. The consistency of this mass was as firm as that of carcinoma and there was adherence of the overlying skin. Because of the presence of these signs and the failure of the mass to disappear after this long interval it was deemed unsafe to withhold exploration. A wide local excision was performed and microscopic examination revealed the typical morphologic appearance of plasma cell mastitis.

GROSS AND MICROSCOPIC FEATURES

Cross-section of a breast which is the seat of plasma cell mastitis shows numerous dilated ducts and minute cysts which, under pressure, exude a thick, creamy, puriform material. In some areas there may be soft, almost necrotic, grayish foci. The tissue often presents a peculiar, pink inflammatory appearance. Cicatricial areas and chalky points characteristic of carcinoma are absent. The process is diffuse, and no discrete tumor can be palpated except in the late stages of the disease when all acute and subacute changes have disappeared. Xanthomatoid foci varying from 1 to 3 mm in width may project from the cut surface. Because of the extreme induration and resistance, the tissues resemble carcinoma and a distinction between the two lesions by palpation alone is exceedingly difficult.

The essential microscopic changes consist of an active, acute and subacute exudative inflammation with numerous leukocytes, lymphocytes and plasma cells. The exudate is especially prominent about ducts and acini, where the cellular reaction may consist almost exclusively of plasma cells. Giant cells of a foreign body type are often present about these foci. These may be few in number, or they may form a striking part of the histologic structure. The dilated ducts are

⁴ Cohn L. C. and Bloodgood J. C. Chronic Lactation Mastitis. Suppurative and Non-Suppurative. *Am J Cancer* 16: 487 (May) 1932.

filled with desquamated epithelial debris. In some areas the epithelial cells undergo an intense malignant looking hyperplasia, which, in the frozen section, may be difficult to distinguish from carcinoma, but which on paraffin section proves to be confined within normal boundaries of ducts and acini (fig 1)

DIAGNOSIS

The most important diagnostic aid in differentiating plasma cell mastitis from carcinoma is the acute onset of the disease and its subsequent clinical course. During the initial stage the entire mammary gland is firm, indurated and diffusely tender. The skin is red and edematous, and the axillary lymphatic glands are enlarged, confluent and tender. There is moderate fever, and the patient presents the picture of an acute or subacute infection. From this state the clinical course is one of slow but continuous regression and not progression as invariably occurs in carcinoma. The disappearance of the acute and later the subacute inflammatory phases and the slow but definite regression of the tumor differentiate it from carcinoma. Thus it is important to emphasize that during the subacute or chronic stage a single examination leads invariably to an erroneous diagnosis, and it is only by a careful history of the onset and progress of the disease and by repeated periodic examination with actual measurements of the tumor that the true nature of the confusing and misleading cancer-like lesion can be established.

Plasma cell mastitis must be distinguished from (a) inflammatory carcinoma, (b) diffuse duct carcinoma and (c) traumatic mastitis.

In the first stages of plasma cell mastitis the clinical picture closely resembles inflammatory carcinoma. In inflammatory carcinoma however, the invasion of the subdermal lymphatics by cancer cells gives rise to an irregular thickening of the skin which is not present in plasma cell mastitis.

Diffuse duct carcinoma may simulate plasma cell mastitis, especially in the presence of a superimposed inflammation. The sudden onset, acute inflammatory signs and symptoms and regression of the lesion are the distinguishing features of plasma cell mastitis. Duct carcinoma is slowly but steadily progressive.

The interpretation of the histologic structure associated with plasma cell mastitis may be confusing and difficult particularly if a diagnosis is attempted by means of the frozen section. The disorderly and atypical epithelium often gives the appearance of having invaded outside structures when actually it is confined within normal boundaries. Another source of confusion is that large edematous plasma cells poorly fixed in the frozen section may resemble superficially small anaplastic carcinoma cells. Careful microscopic examination of these areas with the high power lens of the microscope usually establishes the true nature of these cells.

PROGNOSIS

Plasma cell mastitis is a curious, unexplained inflammatory process and tends to spontaneous regression and disappearance. I have observed a number of examples in which breasts presenting the aforementioned clinical features have returned to an apparently normal state. Courtin and Coquet reported similar observations in which local applications and rest were the only therapeutic measures. In most patients suffering from this condition the breasts have been removed under the

clinical diagnosis of carcinoma, and the true nature of the disease has been discovered only after operation. There is no evidence that this lesion bears any relation to mammary cancer. The intense epithelial hyperplasia which accompanies the acute inflammatory stage has remained confined within the normal boundaries of ducts and acini in all examples which I have studied.

TREATMENT

If the patient is seen during the acute stage of the disease, local applications and rest are the logical methods to adopt while the lesion is watched carefully. If the course of the disease confirms the diagnosis, operation should be withheld as long as there is discernible clinical improvement. If, after a period of observation, the lesion remains stationary or shows signs of progression and the diagnosis becomes uncertain, an exploratory operation should be performed unless the presence of inflammatory carcinoma is suspected. Operation during the acute stage of the process is contraindicated in any event, and neither a local nor a radical procedure should be attempted at this period.

Fig 1—Photomicrograph showing cross section of duct surrounded by a periductal inflammatory process consisting of lymphocytes, leukocytes and plasma cells. This inflammatory process occurred in a breast which exhibited all the classic clinical signs of cancer.

During the later stages, when all signs of acute and subacute inflammation have disappeared and a discrete tumor mass persists, wide local excision is the safest method to pursue. Two considerations lead to this position. First, excision of the mass removes a pathologic lesion, the future course of which no one can foretell, and, second, microscopic examination of the specimen confirms the diagnosis and rules out the presence of carcinoma.

TRAUMATIC FAT NECROSIS

Extraperitoneal fat necrosis was described by Shattock⁵ in 1896 in a lipoma of the thigh, and by Targett⁶ in a lipoma of the breast. According to Hadfield,⁷ who has reviewed the literature on this subject, Lanz,⁸ Heyde⁹ and Kuttner¹⁰ each observed

5 Shattock S G Saponifying Necrosis in a Lipoma of the Thigh, *Tr Path Soc London* 47 246 1896

7 Hadfield G Fat Necrosis of the Breast *Brit J Surg* 17 673 (April) 1930

8 Lanz Traumatic Fat Necrosis *Centralbl f Chir* 25 1253 1895

9 Heyde M Zur Kenntnis der subkutanen Fettgewebnekrose *Deut'sche Zeitschr f Chir* 109 200 1911

10 Kuttner W Ueber circumscribte Tumorbildung durch abdominale Fettnekrose und subcutane Fettspaltung *Berl Klin Wchnschr* 1 9 1913

similar lesions in the subcutaneous tissues of the thigh and in abdominal and extra-abdominal fat. It remained for Lee and Adair,¹¹ however, to point out and emphasize the similarity between the clinical signs of fat necrosis of the breast and those of cancer. In a report of twenty cases, they established the disease as a clinical and pathologic entity (fig 2).

In 1930 Hadfield⁷ reviewed the literature and found forty-two fully recorded cases, to which he added three

Fig 2—Photomicrograph showing foreign body giant cells, lymphocytes and plasma cells in a breast which was the seat of fat necrosis. This lesion induced all the clinical signs of cancer.

of his own. An additional case was recorded by Enzer¹² in 1931.

Traumatic fat necrosis is most common during the fourth and fifth decades, it has been noted in newborn infants and has been due to injury sustained at birth. It may or may not be associated with lactation. Hadfield found a definite history of trauma in 40 per cent of his cases, and Lee and Adair in 70 per cent. Pain and tenderness occur but are not constant. The mass which appears in the breast increases in size. The progressive increase in size, firmness and frequency of adherence of the skin suggest the presence of cancer to such extent that in 26 per cent of the forty-five collected cases (Hadfield) a radical amputation of the breast was performed. Retraction of the nipple occurs in 10 per cent of the cases.

The gross characteristics of the lesion are striking and depend on the stage during which the examination is made. On cross-section the surface is opaque and yellowish white and follows the contour of one or two fat lobules. The central portion of the lesion is frequently cystic, especially in the later stages, and contains an oily yellowish material. In older lesions there are usually small, chalky foci, and in still older lesions, punctate areas of calcification may be discovered.

In cases in which injury is a prominent feature and in which the tumor seems to appear at the exact site of the trauma, I have found transillumination of the

breast a helpful diagnostic aid. The opacity under these circumstances is characteristic of hematoma and differs from the shadow cast by a solid tumor of the breast in which interstitial extravasation of blood does not occur. In several cases the patients were examined at repeated intervals over periods varying between three and six months. Coincident with the diminution in size of the palpable mass, transillumination showed a slow but continuous diminution in the extent and intensity of the opacity, followed by a complete disappearance of the shadow (fig 3).

FIBRO-ADENOMA (THE PRESENCE OF A SINGLE TUMOR IN ONE BREAST)

Errors in differential diagnosis between fibro-adenoma and carcinoma occur, as a rule, under two circumstances: (a) A small, circumscribed, movable isolated tumor exhibiting no attachment to the skin and no visible retraction of the nipple occurring in a young woman often leads to the clinical diagnosis of fibro-adenoma when actually the lesion is carcinoma, (b) a slowly growing, firm, circumscribed, movable tumor exhibiting no attachment to the surrounding structures in spite of its size, frequently situated close to the nipple and areola in the breast of a woman about 50 years of age, many times leads to the diagnosis of fibro-adenoma when actually the lesion is a duct carcinoma.

The only safe method to adopt under these circumstances is to regard the presence of a single tumor in one breast of a woman over 25 years of age as carcinoma until proved otherwise. Under no circumstances should an exploratory operation be performed unless the surgeon is prepared either alone or with the aid of a pathologist to establish the diagnosis at the operating table and proceed with the radical operation if carcinoma is discovered. The exploratory operation should be performed with all precautions against dissemination of tumor cells, and the line of excision

Fig 3—Photomicrograph showing fatty acid crystals surrounded by an inflammatory process including foreign body giant cells.

should extend well beyond the palpable tumor. The wound should be washed with corrosive mercuric chloride in a dilution of 1:500.

MULTIPLE TUMORS IN ONE OR BOTH BREASTS

The presence of more than one tumor in one or both breasts immediately throws the weight of evidence against carcinoma and favors the diagnosis of a benign lesion. Under these circumstances the diagnosis lies

11. Lee B. J. and Adair F. E. Traumatic Fat Necrosis of the Female Breast and Its Differentiation from Cancer. *Ann. Surg.* 72: 189 (Aug.) 1920. A Further Report on Traumatic Fat Necrosis of the Female Breast and Its Differentiation from Cancer. *Surg., Gynec. & Obst.* 34: 521 (April) 1922. Traumatic Fat Necrosis of the Female Breast and Its Differentiation from Cancer. *Ann. Surg.* 80: 670 (Nov.) 1924.

12. Enzer N. Traumatic Fat Necrosis of the Breast. *Am. J. Surg.* 12: 102 (April) 1931.

between two possibilities (1) multiple fibro-adenomas and (2) multiple cysts. When cysts are deeply situated and tense, fluctuation cannot be elicited, and this important differential sign is excluded. Transillumination usually helps to establish the presence of clear fluid cysts, but in exceptional examples an absolute decision as to the precise nature of the lesion may be impossible except by surgical exploration.

It is necessary to point out the importance of establishing the nature of the lesion under these circumstances. The subsequent history of fibro-adenomas that are not removed includes their enlargement, the development of cystic complications and the superimposition of sarcomatous changes. The occurrence of carcinoma in fibro-adenoma is very rare, as is also the sarcomatous transformation of fibro-adenoma.

On the contrary, cystic disease of the breast, especially when complicated by the neoplastic process giving rise to Schimmelbusch's disease, is a serious lesion. With few exceptions multiple palpable cysts in a breast are accompanied by smaller microscopic cysts. The extent to which the epithelial changes have progressed in the walls of such ducts and cysts is impossible to determine clinically. In fact, a malignant epithelial neoplasia which has transgressed its normal boundaries may already exist without giving clinical signs. In the presence of multiple tumors this event is rare but cannot be excluded.

The danger of multiple cysts is far greater than that of multiple fibro-adenomas, consequently a conservative surgical procedure is justified for fibro-adenomas and not for multiple cysts. One of the commonest errors that is made during operation on the breast is the attempted local removal of multiple palpable cysts, a portion of the breast which is the seat of numerous smaller microscopic cysts being left. The fallacy of this procedure is that once a cyst becomes clinically palpable, it is usually not subject to malignant change, as the epithelium in the larger cysts is usually degenerated. In the smaller cysts the epithelial cells are more active and respond more readily to whatever stimulus induced malignant transformation. To remove the larger cysts and leave the smaller ones is to remove the innocent lesions and leave behind the lesion in which carcinoma is most likely to be present or to develop subsequently.

These circumstances render it highly important to establish the differential diagnosis between multiple solid tumors (fibro-adenomas) and multiple cysts in order to plan the scope of the operation in the treatment of these patients.

When after palpation and transillumination, there still remains a doubt as to the diagnosis, the solid or cystic nature of the lesions must be established at operation.

Before proceeding with the incision, a fine needle inserted in one of the masses usually establishes the diagnosis. An incision over the mass down to the outside wall of the tumor reveals the blue dome of the cyst which Bloodgood has so often emphasized or the solid nature of the tumor when fibro-adenoma is present. When the solid or cystic character of the lesion has been established the line of procedure is clarified. For widespread cystic disease of the breast local mastectomy is the only sound procedure to adopt. I recognize that cystic degeneration may occur in fibro-adenomas but these tumors are secondary and do not constitute the essential process as do the cysts in primary cystic disease of the breast (Reclus' disease).

HEMORRHAGIC AND SEROHEMORRHAGIC DISCHARGES FROM THE NIPPLE (BLEEDING NIPPLE)

The problem of diagnosis and treatment of breasts exhibiting spontaneous seroheorrhagic discharge from the nipple is becoming increasingly difficult. Formerly, when patients complaining of this sign came under observation after a mass had already become palpable, the diagnosis of duct carcinoma was simple and the line of procedure clear. As the laity has become educated and warned, the majority of women who now come under observation for this sign apply for treatment so early that no palpable lesion can be detected in the breast. The diagnosis of duct papilloma is justified in these cases with the unfortunate exception that an extremely early duct carcinoma cannot be ruled out completely. I have seen one example of this type in a breast in which no tumor could be palpated.

Transillumination is a diagnostic aid in localizing duct papillomas in the breast. In some cases, however, the papillomas are so small that no shadow can be detected on transillumination. This is especially true when the discharge is essentially serous.

Fig. 4.—Drawing showing multiple duct papillomas (A and B) in the region of the nipple and the areola. No tumor could be palpated in this breast on clinical examination. Transillumination indicated opacities at these sites.

In older women in whom a hemorrhagic discharge from the nipple is more likely to be associated with duct carcinoma or in whom a duct papilloma is more likely to be complicated by carcinoma, especially in the presence of suggestive nodularity in the breast, wide surgical excision or local mastectomy is the safest method to adopt.

In younger women in whom the presence of carcinoma is less probable and to whom the loss of the breast is of greater concern, I do not feel justified in adopting such radical measures. On the other hand, I take the view that to permit such a lesion to remain untreated is a dangerous attitude to assume.

For younger women suffering from a serous or seroheorrhagic discharge from the nipple especially when localization of the lesion is impossible or uncertain, the only methods heretofore available have been either to institute no treatment or to remove the entire breast. Surgical exploration of the breast with an attempt to perform a local excision of the lesion is exceedingly difficult and frequently unsuccessful.

These circumstances led me to consider the feasibility of treating the underlying lesion by means of interstitial

irradiation (removable platinum needles) It seemed that this method, which has met with a certain degree of success in the treatment of mammary carcinoma, should be even more efficacious in the treatment of duct papillomas or of early duct carcinomas, should they exist This method possesses the advantage of avoiding removal of the breast in young women, to many of whom the surgical procedure constitutes a considerable psychologic shock It possesses the disadvantage of not permitting microscopic confirmation of the diagnosis The safety of this method as regards the future development of cancer is impossible to establish for many years

To me this method appears sound on the basis of knowledge of the effects of this treatment on lesions which are already fully developed cancers

Two patients suffering from serohemorrhagic discharge from the nipple who refused to permit any operative procedure have been treated by this method In both, the treatment resulted in complete cessation of the discharge for eighteen months and eight months, respectively This method is suggested in selected cases in young women A fuller report on this problem with details of dosage and technic is in the process of preparation

It is important to confine this method to a distinctly limited group of patients For the present it should not be executed in women with breasts in which subsequent lactation is likely to occur The method should be confined particularly to breasts exhibiting a serous discharge from the nipple in which no palpable tumor can be discovered, and particularly in which transillumination fails to reveal a shadow It would be exceedingly dangerous and unwise to apply this method indiscriminately to all breasts which are the seat of serohemorrhagic discharge from the nipple

ABSTRACT OF DISCUSSION

DR FRANK W. HARTMAN, Detroit For a good many years I saw papillomas in different parts of the breast particularly about the nipple and considered them benign I was taught to believe from my own work, that they were rather innocuous and that a bleeding nipple and the finding of a papilloma constituted a good prognosis More recently though, I have seen a number of breast papillomas that were benign in one area and malignant in another Last year I saw three of these papillary adenocarcinomas apparently developing on the basis of a papilloma of the duct, so that the papilloma question becomes much more important The question of a diffuse invasion of the duct and of malignant degeneration is to be kept in mind, rather than the old idea of a benign lesion without any danger of subsequent malignant degeneration

DR J. J. MOORE, Chicago I am sure that pathologists enjoyed hearing a pathologist tell of the difficulty that may be encountered in differentiating grossly similar breast conditions by rapid frozen sections I had a case of plasma cell tumor of the breast three months ago which clinically simulated a carcinoma and was diagnosed as such The lesion was just over the pectoral muscle The rapid frozen section here fortunately, made the diagnosis without much difficulty It did not have the marked hyperplasia that Dr Cutler showed in his last slide, which gives so much trouble at times in differential diagnosis I wish that Dr Cutler would discuss more fully the different procedures he would employ in multiple adenofibromas and in the cystic conditions Six months ago I saw a case of fat necrosis of the breast but this was in a case of carcinoma and followed a trauma, in which x-ray needles had been applied There were multiple areas of fat necrosis throughout the entire breast, some as large as 2 cm. in diameter

DR J. SHELTON HORSLEY, Richmond, Va. The lesions that Dr Cutler has drawn attention to so vividly are extremely

interesting to the pathologist and also to the surgeon While I don't know very much about pathology, I examine tissues from my operative cases for the fun I get out of it I don't see how I could differentiate between cancer and hyperplasia in one of those slides that he showed The thing that seems to impress me more is that in both fat necrosis and in the inflammatory lesion there are practically always foreign body giant cells In any section in which one finds foreign body giant cells it might be well to be a little conservative in making a diagnosis of malignancy From the surgical standpoint, I am wondering whether the application of fairly intensive roentgen therapy in these cases would be of benefit Certainly it would be very helpful in carcinoma I am wondering whether this type of inflammation would not also be benefited by roentgen therapy such as, for instance, boils or similar inflammatory processes are

DR ARTHUR F. ABT, Chicago I should like to ask Dr Cutler whether he knows of any relationship between the type of plasma cell mastitis that he has described and the benign prepuberty breast hypertrophy or mastitis in children

DR MAX CUTLER, Chicago Dr Hartman has raised the important question of the treatment of bleeding nipple There have been diametrically opposite opinions among authorities on the treatment of hemorrhagic discharges from the nipple ranging from the one extreme that the lesion is innocuous and requires only observation to the other extreme presenting the opinion that complete mastectomy should be performed This divergence of views on a problem of such practical importance is unfortunate and confusing particularly to those who have had a limited experience with this type of lesion During the last few years the evidence that has accumulated has definitely caused a shift of opinion in the direction of regarding this sign with greater suspicion Most authorities now agree that the lesion underlying "bleeding nipple" is potentially dangerous and should be treated Although the lesion may not be carcinoma when first seen, I think that most observers are now of the opinion that it is a danger signal and potentially cancerous In two examples that I have seen an early duct carcinoma was already present although no tumor could be felt in the breast Dr Moore has raised the question of the difference in treatment of multiple fibro-adenomas and multiple cysts The prognosis of the former is excellent whereas the prognosis of the latter is problematic Having established that multiple lesions of a breast are fibro-adenomas I pursue a conservative policy Cystic disease of the breast is potentially dangerous and having established that nodularity is due to cysts I resect that portion of the breast which is the seat of disease or remove the entire breast when there is diffuse and generalized involvement The most frequent error that is made in this respect is to remove the palpable cyst which is the least dangerous and leave behind numerous microscopic cysts which not infrequently become the seat of cancer In response to Dr Horsley's question I may state that I have irradiated one breast which was the seat of plasma cell mastitis and found that the lesion regressed rapidly without suppuration In response to Dr Abt's question I know of no relation between plasma cell mastitis and mammary hyperplasia in the new-born The former is surely an infective process, and the latter distinctly a physiologic one In closing I wish to emphasize that the use of interstitial radiation for bleeding nipple must be limited to selected cases Until more data have been accumulated it is safest to confine this method to the treatment of patients who refuse operation It should not be employed in the treatment of a breast that may in the future become the seat of a lactation One disadvantage of the method is that the presence of carcinoma cannot be established or excluded microscopically as can be done by surgical excision The important question that remains to be answered is whether the irradiation is adequate to sterilize an early duct carcinoma should this state be present at the time of treatment

Two and a Half Colds a Year—Epidemiological studies indicate that on the average every man, woman and child in the United States experiences about two and a half colds each year—Dochez, A. R. AN UNUSUAL HEMATOLOGIC REACTION TO NEOARSPHENAMINE

MURRAY L. RICH, MD

Instructor in Medicine University of Cincinnati College of Medicine
Resident Physician Cincinnati General Hospital

CINCINNATI

During recent years, numerous reports of blood dyscrasias occurring in the course of the arsenical treatment of syphilis have appeared in the literature. Although they are undoubtedly of rare occurrence, as indicated by Cole and his co-workers,¹ who found only two such complications in a series of 78,350 injections given to 1,212 patients, they are of sufficient interest to have attention drawn to them.

McCarthy and Wilson² recently reviewed seventy-nine cases and added two more of their own. From their analysis of this series they concluded that there are three main divisions into which these cases can be divided: (1) thrombocytopenic, (2) granulocytopenic and agranulocytic and (3) aplastic. The chief symptoms of the first group, purpura and bleeding, appeared immediately or within four hours in seven of the twelve cases, while the symptoms of the other two groups as

Stephens³ stated that it seemed probable that the temporary thrombocytopenia accompanied by slight transient decrease in the red and white cell count were due to peripheral factors rather than to any effect on the bone marrow. Jui Wu Mu⁴ found a temporary diminution in the number of circulating platelets in patients receiving neoarsphenamine. This diminution appeared in from ten to thirty minutes after injection and was followed within six hours by a slight compensatory thrombocytosis of from one to three days' duration.

Although it is apparent from these reports that the circulating platelets probably can be destroyed by the arsphenamines, it would be peculiar if the other elements of the blood should escape its action. Moore and Keidel⁵ observed several patients with only prodromal symptoms of a reaction, and in each they found a decrease in neutrophil cells, with an eosinophilia of from 5 to 8 per cent, a slight increase in monocytes, and the presence of numerous fragile leukocytes. In another paper they⁶ state that the dermatitis following arsphenamine is usually accompanied by blood changes, consisting chiefly of leukopenia, a decrease in the number of neutrophils, an eosinophilia, a monocytosis, and the appearance of many fragile leukocytes. They do

a rule did not appear for several days or weeks. They state that the arsphenamines appear to have at least two separate effects, the one a depression of bone marrow function and the other a toxic action on the blood platelets in the peripheral circulation. While the benzene radical may be the causative factor in the production of depressed bone marrow function, they state that it cannot be held responsible for the acute thrombocytopenic cases. In this group there is no evidence of depressed bone marrow function, the destruction of platelets is an acute and a peripheral phenomenon. Their rapid regeneration speaks against any specific toxic action on the megakaryocytes.

This concept of a toxic action on the circulating platelets had previously been stated by other workers. Smith⁷ described a case of acute purpura appearing immediately after an injection of neoarsphenamine. Although no examination was made at the time of the reaction, he suggested that the symptoms might be due to a sudden diminution in the platelets and an almost as prompt recuperation—a so-called platelet crisis.

not state whether these changes in the white cells are due to some aberration of marrow function or to a disturbance of the circulating cells.

Recently we have observed a patient in a reaction following neoarsphenamine in whom there was an immediate purpuric eruption. A blood smear taken a few hours later showed a very definite thrombocytopenia, and in addition there were neutrophilic cells showing changes which we believe are probably due to some direct toxic action in the circulating blood.

REPORT OF CASE

A young white woman aged 18 first came to the outpatient clinic of the Cincinnati General Hospital in December, 1931, complaining of trouble with her eyes. A diagnosis of syphilitic interstitial keratitis was made probably on the basis of congenital syphilis, and she was referred to the venereal clinic for treatment. She was faithful in returning for treatments and in the course of the next fourteen months she received three courses of bismuth compounds, one course of mercurial oil and two courses of neoarsphenamine. She was given a total of fourteen injections of neoarsphenamine of 0.5 Gm each in February and March 1933; she was allowed a rest period and received no treatment. She returned to the clinic early in

E. and Keidel Albert. *Dermatitis and Allied Reactions Following the Arsenical Treatment of Syphilis*. Arch. Int. Med. 27: 716 (June) 1921.

April, and another Wassermann reaction was taken, which was strongly positive. Consequently, on April 7 another course of neoarsphenamine was started. She received 0.5 Gm, and one week later 0.3 Gm. Almost immediately following this injection she became unconscious. She was given an injection of epinephrine and recovered consciousness but was quite delirious. Then there developed a number of purpuric spots over her entire body, which were most marked around her eyes, over the chest and in the conjunctivae. The delirium passed away during the course of the next half hour, and she was sent into the hospital.

This was followed by a rapid regeneration of these cells, either as a compensatory reaction or due to a stimulating effect on the marrow by the neoarsphenamine. Certainly, there could be no toxic depression of the marrow activity in the presence of such evidence of regeneration. Likewise, the reduction of platelets must have been due to some peripheral action. Their prompt reappearance in the blood stream within the next four days preclude the possibility of any specific toxic action on the megakaryocytes.

A cell illustrating the band form that made up the majority of the neutrophils. B, C, D, E, and F neutrophils that had undergone various degrees of destruction, G a small lymphocyte that had undergone some degeneration. The drawings were made by Miss Mary Maciel.

Examination at that time showed the purpuric spots previously mentioned. There was some clouding of the cornea of the left eye. The upper teeth showed the central notch in the incisors characteristic of inherited syphilis. The heart and lungs were normal. The pulse was 90. The blood pressure was 110 systolic, 60 diastolic. The liver edge was palpable two fingerbreadths below the costal margin. The spleen was not felt, though the next day the edge was just palpable. The uterus was enlarged, the fundus extending to the navel, there being a four months pregnancy. The extremities were normal. A blood count and smear were taken just after her admission.

The next day the patient was much improved. No new purpuric spots appeared. Within two days she felt perfectly well and was discharged from the hospital, recovered, one week after admission. She was seen again one month later. At that time she was feeling well except for a recurrence of the interstitial keratitis. No more purpuric manifestations had appeared.

The blood counts are recorded in the accompanying table. A urine examination the day after admission showed the presence of a moderate amount of albumin and numerous red cells. These disappeared after twenty-four hours and thereafter the urine was normal.

The smear taken on the admission of the patient to the hospital showed an interesting picture. The platelets were markedly decreased in number as judged from the slide, though unfortunately no count was made. The neutrophilic leukocytes showed evidence of marked regeneration. There were numerous myelocytes and metamyelocytes and the remaining cells were mostly of the band form. In addition to this there were 75 per cent of degenerated neutrophils. These cells were smaller than normal, some being no larger than red cells. The nuclei were pyknotic, the chromatin being condensed into small deeply staining globules. The granules in the cytoplasm could not be made out in some of the cells and in others only a few coarse granules persisted. There was vacuolization of the cytoplasm in some of these cells.

The majority of the lymphocytes did not undergo the changes suffered by the neutrophils. Two or three were seen, however, which showed evidence of some damage. The nuclei were shrunken and somewhat pyknotic and the cytoplasm seemed to have undergone some condensation. The few platelets that were seen appeared normal. No evidence of damage to the red cells was observed.

Smears taken the next morning did not reveal any of these degenerated cells. The myelocytes and metamyelocytes had practically disappeared from the picture. There was a very high percentage of neutrophils, however, a differential count revealing 92 per cent.

COMMENT

To us, these changes indicated a rapid destruction of the circulating neutrophils by the neoarsphenamine.

SUMMARY AND CONCLUSION

In a case of acute thrombocytopenic purpura following an injection of neoarsphenamine, a smear taken three hours after the injection showed, in addition to the thrombocytopenia, the presence of numerous degenerated neutrophilic cells. There was also evidence of intense marrow stimulation. These conditions quickly disappeared. It is concluded that neoarsphenamine at times has not only a toxic depressant action on the bone marrow but also a destructive action on some of the circulating elements of the blood, and that the neutrophilic cells as well as the platelets are susceptible to its action.

Clinical Notes, Suggestions and New Instruments

COMMUNICATION BETWEEN THE TWO PLEURAL SACS, WITH LUNGS SHOWING TUBERCULOSIS HEALED AFTER THORACOPLASTY

CHARLES R. SMITH, M.D. AND H. S. WILLIS, M.D.
NORTHVILLE, MICH.

Demonstrable interpleural communications in man are notably uncommon. The anatomic basis of such natural and spontaneous phenomena is not clear. However, the basis for possible rupture or mechanical break does exist in the anatomic structure of the mediastinum. This has been studied in some detail by Nitsch,¹ who described two "weak" places in the structure of the mediastinum—one posterior to the upper portion of the sternum at the level of the second, third and fourth ribs and the second in the posterior inferior portion of the mediastinum near the level of the eighth rib. When there is a pneumothorax with high pressure or when a pleural exudate is present the mediastinum in the latter region may bulge to the opposite side suggesting hernia. In the presence of pneumothorax with excessive pressure particularly if adhesions are present the possibility of a pleural tear in either of the weak places must be considered.

One instance of interpleural communication in man has been described by each of the following authors: Julien², Dumarest

From the Wm. H. Maybury Sanatorium (Detroit Municipal Tuberculosis Sanatorium).

and Bonafe,³ Dumarest and Marinet⁴ and Johansohn and Proctor.⁵

Recently, an opportunity has been afforded us to study a case of this condition

REPORT OF CASE

A man, aged 35, Polish, had had acute renal disease in 1926, with frequency and albuminuria. At this time he complained of a dry cough, which gradually became productive, ease of fatigue, and loss of weight. A roentgen study of the lungs at this time did not reveal pulmonary tuberculosis. Following this episode, he was symptomatically well until October, 1928, when he noticed swelling of his ankles, greater fatigue, and a more productive cough. A diagnosis of tuberculosis of the left lung was made in December, 1928, and he was admitted to a hospital. In May, 1929, on admission to the Wm H Maybury Sanatorium, roentgen and physical examination revealed pulmonary tuberculosis which involved the whole left lung. The sputum contained tubercle bacilli. The urine showed a great deal of albumin and a few pus cells, a few red cells, and a few hyaline and granular casts. The specific gravity varied from 1.025 to 1.017. The red blood cells numbered 3,910,000. The hemoglobin was 74 per cent. The white blood cells fluctuated between 11,040 and 15,640 with a normal differential count. Analyses of the urine changed but little during his stay here. Guinea-pig inoculation with urinary sediment was negative for tuberculosis. The blood pressure was 110 systolic, 80 diastolic, on admission.

July 16, an attempt was made to induce pneumothorax on the left side. The initial pressure ranged between -4 and -8 , and after the introduction of 400 cc of air the pressure was between 0 and -4 . Immediately after this the patient complained of pain in the right side of the chest. The following day, 240 cc of air was introduced, the final pressure being

left. A total of 500 cc of air was introduced at this time. The pressures before introduction of air were, on the left, between $+2$ and -5 on the right, between $+1$ and -4 . After 500 cc of air was introduced into the left side, the pressures were left, between $+6$ and -5 right, between $+4$ and -6 . Roentgen studies on this date, before and after introduction of air (figs 1 and 2) show the increase in pneumothorax on the right side after introduction of air into the left side.

August 21, a left phrenicectomy was done preliminary to a thoracoplasty, which was performed in three stages in December, 1929, and January, 1930. From this time, the pulmonary tuberculosis was a relatively unimportant part of the picture. The sputum decreased to a very small amount and was negative for tubercle bacilli after April, 1930. Symptoms of chronic nephritis with edema developed and became extreme. Convulsions occurred. The blood pressure at this time was 230 systolic, 150 diastolic. Chemistry studies of the blood added nothing of specific interest. The patient died, March 6, 1932, twenty-seven months after thoracoplasty was performed.

Postmortem Examination

—There was marked anasarca of the body and marked thoracic deformity from operation. Before the body was opened, 800 cc of methylene blue solution was injected into the right pleural space in an effort to find the communication that had existed before thoracoplasty was performed. No channel of communication could be

Fig 1.—Degree of collapse on the right before left-sided pneumothorax refill Aug 6 1929

Fig 2.—Degree of collapse on the right immediately following introduction of 500 cc of air into the left side Aug 6 1929

Fig 3.—Collapsed left lung. The collapse of the whole lung and the marked retraction of the apex are clear. Much of what appears at first view to be apical pulmonary tissue represents mediastinal contents. The arrow indicates the pigmented pleural line which separates lung from mediastinal structure. Although the lower half appears slightly darker than the upper the texture and appearance is similar in all parts of the specimen.

between $+6$ and -6 . On the three following days 250, 400 and 250 cc of air respectively were introduced, the final pressure being between $+7$ and -4 . Fluoroscopic examination revealed no apparent collapse of the left lung, but the right lung was entirely separated from the chest wall by a thin layer of air. This was confirmed by roentgen studies. July 29, 400 cc of air was introduced into the left side which increased the collapse of the right lung by about 50 per cent as seen by the fluoroscope. August 6 a needle was introduced into each pleural space and a series of manometric readings made before and after the introduction of various amounts of air into the left side. It was found after introduction of air that the pressures of the two sides increased together, the changes in pressure on the right lagging slightly behind those on the

found. However, this is not surprising for the left lung was tied firmly to the mediastinal structures and the left pleural space was entirely obliterated by adhesions.

The left lung was contracted to approximately one-fifth its original volume. It was atelectatic, like basteak in consistency, and noncrepitant. There were a few minute calcified nodules throughout the base. No signs of active tuberculosis and no cavity was present and there was much gray-white scar tissue (fig 3). The right lung was voluminous and markedly edematous and appeared entirely free from tuberculosis.

The remainder of the autopsy revealed cardiac hypertrophy, vascular sclerosis, large white kidneys and ascites. There was no evidence of tuberculosis.

The account of the histologic examination will be confined to that of the lungs. Fibrosis and scar tissue were taken as the criteria of previous disease. In areas of former disease,

the scar tissue was dense for the most part, but in some areas it was more or less diffusely scattered, with fibers coursing in alveolar walls and alveolar exudate. The latter, often partially organized, contained numerous large, oval, mononuclear cells and many small round cells. The large bronchi showed considerable lymphoid cell infiltration in their walls. The smaller ones were distorted and well-nigh obliterated by scar tissue. Some had retained their columnar epithelium, others had a

Fig 4—Section of completely collapsed area. Special stains reveal the presence of many elastic tissue fibers indicating that the collapsed area originally contained some degree of disease.

lining quite like flat alveolar epithelium. In some, the mucosa had been shed in part or in toto. There was considerable fat in and just under the greatly thickened pleura in the apical region, particularly on the mediastinal aspect. Figure 4 illustrates the microscopic appearance of an area that contains a moderate amount of scar tissue.

Fig 5—Section of semicollapsed area. The compressed and denuded alveoli, the cells and the cylindric capillaries are described in the text.

For the most part, in the nondiseased areas, the pulmonary tissue was partially collapsed, but in many places it was in a state of virtual atelectasis. Depending on the degree of collapse, alveoli were linear, long and very narrow, or they were more or less completely obliterated by pressure or were filled with large granular monocytes (epithelioid cells), small lymphoid cells and other small round cells of nondescript order. In such areas, the walls were thickened, the epithelium was

intact in part and denuded in part. Throughout, the capillaries in the alveolar walls were large, circular in cross-section, and almost entirely devoid of blood. Throughout the lung, the arteries were greatly thickened and possessed an abnormally large amount of fibrous and elastic tissue. In nondiseased regions, many of the bronchi showed considerable atrophy. Some of these features are shown in figure 5.

The only report available in the literature on the pathologic end-appearance of the healed tuberculous lung, collapsed by thoracoplasty, is by Staemmler,⁶ who presented data concerning a patient who died of a nontuberculous cause nineteen years after thoracoplasty had been performed. In his case, the tissue at former sites of the disease was distorted and densely scarred, that in nondiseased areas was compressed but not atrophic and was apparently unharmed by the prolonged collapse. Staemmler's impression was that simple collapse leaves the elastic fibers unharmed, while inflammatory reaction leads to their destruction. This has been shown to be true in collapse by pneumothorax.

TRAUMATIC PERFORATION OF THE SIGMOID COLON

MOSES BEHREND, M.D. AND CLINTON S. HERRMAN, M.D.
PHILADELPHIA

All textbooks dealing with the large bowel make mention of the possibility and cite reports of injury by instruments, bougies and other foreign bodies. However, excepting injury by compressed air, the current literature is singularly lacking in such reports. A hasty perusal of the literature for the past ten years failed to present a case similar to ours which we feel warrants the following presentation.

S. W., a white man, aged 45, admitted to Mount Sinai Hospital April 26, 1933 at 1:30 a. m., had been receiving treatment from a naturopath during the past seven or eight weeks for a nasal condition. This treatment consisted of an enema or colonic irrigation. At 8 p. m. of the preceding day (five and one-half hours before admission) while receiving such a treatment he suddenly experienced severe abdominal pain and exhibited the syndrome called shock. The naturopath took him to a physician who administered one-fourth grain (0.016 Gm.) of morphine sulphate by hypodermic injection, without attempting a diagnosis. The patient returned to his home and called another physician, who again symptomatically gave morphine for the pain. After several hours a third physician was called, and he advised hospitalization.

Our examination was made one hour after admission to the hospital, at which time the patient was cyanotic, restless and in extreme pain. The abdomen was distended, rigid and tender, most markedly in the upper right quadrant. No peristalsis could be heard. The temperature was 102 F., respiration rate, 40, pulse, 130. The blood pressure which on admission was 120 systolic, 70 diastolic had dropped to 85/70. The erythrocyte count was 4,350,000, the leukocyte count 3,950. Immediate section was advised with a provisional diagnosis of (1) ruptured colon or (2) ruptured peptic ulcer.

Under spinal administration of 10 mg. of procaine hydrochloride, the abdomen was opened. The peritoneal cavity was distended and completely filled with fluid and feces. Particles of food debris floated on top. Suction apparatus was used to empty the peritoneal cavity. The intestines were inflamed and matted together by exudate. There was a perforation of the sigmoid colon 28 cm. from the anal orifice. The perforation was 1 cm. long with sharply defined margins. To the operator the wall of the intestine appeared of normal thickness without apparent diverticulum, ulceration, growth or inflammation. The wound was closed with a continuous Lambert suture of catgut, reinforced with linen thread. Rubber tubes were placed in the pelvis and the wound was closed by thorough and through silkworm sutures. A transfusion of 325 cc. of whole blood was given. The time of operation was thirty minutes. The patient died at 7 a. m.

6 Staemmler M. Veränderungen des Lungengewebes nach längerer Ausschaltung durch Thorakoplastik. Beitr. z. klin. d. Tuberk. 67: 518 1927.

7 Roubier C. and Doubrow S. Etude histopathologique du mode de l'action du pneumothorax artificiel dans la tuberculose pulmonaire. Rev. de la tuberc. 10: 463 (Aug.) 1929.

Necropsy, performed by Dr D F Meranze, disclosed the following salient features. The peritoneum contained only about 10 cc of blood-tinged fluid. The omentum was hemorrhagic and adherent to underlying coils of intestine, which were markedly congested and adherent to one another. The closed perforation was sealed tight—both air and water proof. There was a small diverticulum 2.5 cm from the perforation.

COMMENTS AND CONCLUSIONS

1 It was impossible to ascertain whether the rupture was caused by a perforation of an instrument or was due to forcible distention by fluid. We are inclined to the former belief because of the incised character of the perforation rather than a ragged tear.

2 The rapidity with which death ensued in this case is cause for consideration. The patient was practically moribund when taken to the operating room seven hours after the accident and died eleven hours after its occurrence. His rapid death, we believe, was the result of the massive absorption of toxins from the concentrated fecal emulsion under pressure. The extremely low leukocyte count likewise bespeaks an overwhelming toxemia.

SPERMATOGENESIS FOLLOWING THERAPY WITH THE
GONAD STIMULATING EXTRACT FROM THE
URINE OF PREGNANCY

WILLIAM L. BROSIUS, M.D., AND ROBERT L. SCHAFFER, M.D., DETROIT

The rapidly accumulating literature on the pituitary gonad relationship and the effects of the gonad stimulating extract from the human urine of pregnancy deals almost entirely with animal experimentation. The entire subject of endocrinology owes its advancement from the speculative phase of the past century to its present level chiefly to the experimentalists. Clinical studies sufficiently controlled to permit careful analysis are relatively few.

The pituitary gonad relationship shows wide species differences even in members of the closely related rodent group—mice, rats, guinea-pigs and rabbits—on which most of the intensive work has been done. When information is considered from the many other species that have been studied—the frog, pigeon, duck, chicken, pig, cow, horse, dog, cat and monkey—wide variations in the mechanisms involved become apparent. This emphasizes the fallacy of predicting reactions in the human being from results obtained by animal experimentation in the pituitary gonad relationship before such results are actually obtained in man. This also adds value to reports of the results of human therapy.

REPORT OF CASE

B. B., a man, aged 33, seen March 21, 1931, complained chiefly of sterility. The patient was apparently normal in every respect until he acquired mumps at 27, with a complicating bilateral orchitis resulting in bilateral testicular atrophy. For the past three years he had noticed an increasing coarse intention tremor, speech hesitation, sluggishness and occasional dizziness. There had been no loss of libido or potentia nor any castration signs such as prostatic or vesicular atrophy, obesity or vasomotor changes.

The patient was 68 inches (173 cm.) tall and weighed 160 pounds (72.6 kg.). Physical examination was normal except for bilateral atrophy of the testes, each of which measured about 18 by 11 mm. and was very soft.

The basal metabolic rate was plus 9 per cent. Chemical and microscopic examinations of the blood and urine showed no abnormalities. The blood gave a negative Wassermann reaction. There was complete aspermia on three examinations of condom specimens over a period of one month.

A preparation of anterior pituitary-like principle from pregnancy urine, 2 cc. (17 rat units per kilogram of body weight), was administered in the gluteal muscle twice a week. Within two weeks there was a definite increase in the size and firmness

of both testes, and at three weeks occasional nonmotile spermatozoa were found. At six weeks there were numerous nonmotile spermatozoa, and at nine weeks large numbers of actively motile spermatozoa were present. The size of each of the testes steadily increased to 20 by 28 mm., and the consistency returned to normal. There was marked subjective improvement, including an increase in capacity for both mental and physical work. The tremor, speech difficulty, sluggishness and dizziness had disappeared.

After twelve weeks, treatment was discontinued. Four weeks later, only a few nonmotile spermatozoa were present, and three weeks later the testes were definitely softer, with only occasional nonmotile spermatozoa demonstrable. Treatment was resumed, and after three weeks a few motile spermatozoa made their appearance. At the fifth week they were present in large numbers and were very active. Numerous spermatozoa and testicular firmness were maintained for a year on a dosage of 2 cc. of the preparation of anterior pituitary-like principle from pregnancy urine once a week. A lapse of treatment for one month resulted in a decrease of spermatozoa and testicular softening. On the resumption of treatment, spermatozoa increased, and the testes became firm. For eight months this condition has been maintained on a dosage of 2 cc. every two weeks.

COMMENT

The gonad stimulating substance from the urine of pregnancy is not as yet positively identified with the sex hormone fraction of the anterior pituitary, and its source is not definitely known. Its physiologic effects are in many ways similar to those of the sex fraction of the anterior pituitary, but there are distinct differences. There are a few positive reports in the literature of spermatogenesis following its administration. Schockaert¹ reports spermatogenesis in the duck. Balawenetz² reports the hastening of spermatogenesis in immature animals. Kraus³ reports hyperplasia of the interstitial cells of the testes and spermatogenesis following administration of Aschheim-Zondek's hormone to male animals. Schapiro⁴ reports spermatogenesis in nine of twenty-six young human males. There are no reports of induced spermatogenesis in the adult human male.

Of the negative reports an outstanding one is that of Engle⁵ who reports an increase in the size of the testes without spermatogenesis in immature monkeys and rats. In a summary of the literature he states that in the male mammal, it is generally agreed that none of these gonad stimulating factors are directly concerned with gametogenesis. The results in the case here presented indicate that man may be an exception to this general statement. The difference in results obtained may be due in part to differences in material used, in dosage and in duration of observation.

It should also be noted that in this case with marked bilateral testicular atrophy and complete aspermia there was retention of libido and potentia, and none of the signs of castration appeared. This would seem to indicate, as is commonly assumed, that the preservation of secondary sex characters, as well as the maintenance of the prostate and vesicles, are directly concerned with the interstitial cell of the testes and not with the tubule.

While generalizations from a single case must always be made with caution, it is possible to infer here that the pituitary did not hypertrophy as in castrates with production of an excess of sex hormone, as this patient responded to therapy with a pituitary-like substance.

SUMMARY

In a case of complete aspermia with bilateral testicular atrophy following orchitis as a complication of mumps, spermatogenesis repeatedly followed the administration of the gonad stimulating extract from the human urine of pregnancy, and aspermia returned on the withdrawal of treatment. This seems to permit the interpretation that in this case the gonad stimulating extract from pregnancy urine stimulated spermatogenesis in a human being.

1304 Kresge Building

The material used was a preparation of anterior pituitary-like principle from pregnancy urine, supplied by Parke, Davis & Co. During the first six months it contained 50 rat units per cubic centimeter; since that time it has contained 100 rat units per cubic centimeter.

DRAINAGE OF A SYRINGOMYELIC CAVITY TWICE
IN THE SAME PATIENT THREE YEARS
INTERVENING

CHARLES H. FRAZIER, M.D., Sc.D., PHILADELPHIA

In these columns almost three years ago, I¹ recorded my experience and the immediate results in the treatment of a syringomyelic cavity by drainage. The operation was performed, April 14, 1930. The cord was exposed by removal of the spinous processes and laminae of the seventh cervical and the first thoracic vertebra. The cavity was drained by an incision just to the right of the median line and, to prevent the lips of the incision uniting, a small strip of gutta percha was interposed. While the patient was seriously crippled, the principal indication for the operation was urinary incontinence. The subsequent history of this case has so many points of interest that I venture to submit it for publication.

In the first place, there has been no recurrence of the incontinence for the relief of which the operation was performed. This, of course, was a source of great satisfaction to the patient. But in the middle of January, 1933, the patient began to have attacks of respiratory embarrassment, both distressing and alarming. In addition, she developed a right-sided ptosis and could speak only in a whisper. Although her condition seemed desperate, we ventured to have her transported by ambulance some 90 miles for readmission to the University Hospital.

It was quite evident from the symptoms as described that the process had extended somewhat cephalad since the first operation. But to assure myself that the syringomyelic cavity had refilled, before consideration of a second operation I decided to explore with a lumbar puncture needle. The needle was introduced at the level of the previous laminectomy and soon penetrated the dural sac. Cerebrospinal fluid escaped freely. The stylet was reintroduced, the needle was advanced and again clear fluid escaped but at a much slower rate, and the rate of flow was not affected by jugular compression. Manifestly, the needle had penetrated the syringomyelic cavity, which had evidently refilled, since about 9 cc of fluid escaped, presumably from the redistended cavity.

If, as we presumed, the drainage opening had closed and the cavity had refilled, the indications for operation were as clear and justifiable as they were in the first instance. Accordingly, February 2, the spinal sac was reopened through the original incision. On inspection there was no trace of the incision made in the cord three years before. On the surface the cord appeared quite normal except at one point where there was an adhesion between the arachnoid and the cord. I selected this point for my incision. The cord was steadied with a small hook and an incision 2 cm long made into the syringomyelic cavity. The second incision must have been precisely at the site of the incision of three years before, for lying in the cavity at that level I saw the tiny strip of gutta percha, which had been introduced at the first operation in the hope of preventing the lips of the chordotomy wound from closing. Evidently, the strip of gutta percha had fallen into the cavity and the wound had closed over it. To prevent the gutta percha strip from being dislodged again, I secured it in place with a silver clip, clamped to the ridge of the chordotomy wound.

During the five months since the second chordotomy there has been a striking improvement. The alarming symptoms have disappeared, the patient's voice has returned, and she can partially open her right eye. She has returned to her former regimen and is carrying on where she left off before the setback in December, 1932.

No attempt has been made to describe in detail the syringomyelic picture. This communication purports only to bring to the reader's attention the experience of a patient with syringomyelia (1) operated on twice, (2) with an interval of three years between the first and second operation, and (3) with striking improvement after each operation, and to call the attention of the medical public to the propriety of resorting to a second operation should there be signs of recurrence or progression of the lesion.

Council on Pharmacy and Chemistry

CLAVIPURIN NOT ACCEPTABLE
FOR N. N. R.

Report of the Council

ON CONSIDERATION OF THE COUNCIL'S ACTION ON CLAVIPURIN, AS SET FORTH IN THE FOLLOWING REPORT AND THE STATEMENT BY THE MANUFACTURER GEHE & COMPANY, THAT THIS FIRM COULD NOT COOPERATE IN MAKING THE PREPARATION ACCEPTABLE GANE & INGRAM, THE AMERICAN DISTRIBUTOR HAS INFORMED THE COUNCIL THAT IT HAS NO INTENTION OF MARKETING CLAVIPURIN IN THIS COUNTRY. AS A CRITICAL ADDITION TO THE LITERATURE ON ERGOT PRODUCTS AND FOR THE INFORMATION OF PHYSICIANS THE COUNCIL AUTHORIZED PUBLICATION OF THIS REPORT.

PAUL NICHOLAS LEECH, Secretary

Clavipurin is a preparation of the alkaloids of ergot (claviceps purpurea) manufactured by Gehe and Co. A. G. of Dresden and marketed in this country by Gane and Ingram. It is stated to contain (in the form of tablets, or as solution in vials and ampules) "the entire complex of the uterus-active alkaloids in exact dosage, in purest and isolated form." No statements appear on the labels of any of the dosage forms as to their alkaloid content or pharmacologic activity in terms of some standard preparation.

The active principles of Clavipurin are claimed to represent ergotamine and ergotinine. According to the claimed method of preparation, the composition of the finished product would vary with the proportions of the alkaloids in the crude drug. The relative proportion of ergotamine and ergotinine present would not be of much importance, as these have practically equal potency, but since ergotamine and ergotinine also occur in the crude drug and are of considerably less activity than the other two alkaloids, the relative amounts of the latter would considerably modify the activity of the preparation. Hence pharmacologic assay would be essential even assuming that Clavipurin contains only the alkaloids and no contaminating substances, which seems unlikely.

At the request of the A. M. A. Chemical Laboratory the firm supplied specimens of Clavipurin powder in addition to the foregoing dosage forms, for assay. In a letter, the firm stated that 0.6 Gm. of Clavipurin powder is sufficient to make 3 Kg. of solution or 1000 tablets. This would represent 0.2 mg. per gram (or approximately per cubic centimeter) of solution, or 0.6 mg. per tablet. In another communication, the firm claimed, further, "Each tablet is guaranteed to contain 0.5 mg. of pure alkaloids." Presumably the powder is intended to represent the pure alkaloids although it is not so stated.

In the "literature" submitted by the firm, the following statements appear as to the alkaloidal content of Clavipurin solution:

0.18 mg. per cc.	(Schubel and Straub)
0.6 mg. per cc.	(Mahn and Reinert)
1.0 mg. per cc.	(Roseno)
5.0 mg. per cc.	(A. Braun)

The only one that approximates the claimed content is that of Schubel and Straub. The Council's referee found no satisfactory explanation of this divergence.

Specimens of Clavipurin powder, tablets and solution were assayed for the A. M. A. Chemical Laboratory by two independent investigators working in different laboratories. One of these workers (designated *a*) assayed the preparations pharmacologically both by blood pressure and by the U. S. P. cock's comb methods against fresh preparations of Fluidextract of Ergot U. S. P. as standard. The other (designated *b*) employed the U. S. P. method, the Broom and Clark method and Smith's Chemical method against ergotamine tartrate crystals as standard. The results obtained are as follows:

1. (a) 75 mg. of Clavipurin powder is equivalent to about 1 cc. of the U. S. P. Fluidextract which represents about 0.05 mg. of ergotamine tartrate. The powder then contains the equivalent of about 0.67 per cent of this alkaloid. (b) 1 mg. of Clavipurin powder is equivalent to from 0.15 to 0.2 mg. of ergotamine tartrate, representing from 15 to 20 per cent. Determinations by *a* and *b* were made on different samples of the powder. The Council's referee has no information as to

whether or not these came from the same lot. This indicates a difference in activity of about 3,000 per cent, if there is doubt as to the validity of the observations, this would seem to apply only to the result obtained by *a*, since the determination of *b* was checked by three different methods. However, in the former, 50 mg had no effect on the cock's comb, which seems to indicate that the first determination was correct and that the specimen used was practically inactive.

2 (a) 1 cc of the solution represents from 0.5 to 0.67 cc of the U S P Fluidextract or is equivalent to approximately 0.25 to 0.34 mg of ergotamine tartrate per cubic centimeter, (b) Clavipurin solution is equivalent to about 0.25 to 0.3 mg ergotamine tartrate per cubic centimeter.

Clavipurin solution therefore appears to represent a little more than half the potency of the U S P Fluidextract Ergot, both the foregoing values exceed that claimed by the firm. Either more of the powder is used for making the solution than is claimed, the powder has deteriorated whereas the solution has not (this appears unlikely), or the solution was not made from powder having the assayed potency.

3 (a) One tablet is equivalent to from 0.4 to 0.75 cc of U S P Fluidextract, representing about 0.2 to 0.38 mg of ergotamine tartrate, (b) one tablet contains approximately 0.315 mg of ergotamine tartrate. These values are about one-half those claimed for the tablets (from 0.5 to 0.6 mg).

In no case therefore, have these independent assays confirmed the claims of the firm, the values found vary from 0.67 to 150 per cent of the claimed potencies.

Clavipurin appears to be practically free of histamine, acetylcholine and tyramine.

The firm, being apprised of these results, replied that Clavipurin is subject to "periodical control examinations by the Pharmacological Institute of Kiel University (Professor in ordinary Dr. Kulz)", and that a recent assay against Gynergen as standard showed two specimens to be equal in activity to and one to have 120 per cent of the potency of Gynergen. Since the reports to the A M A Chemical Laboratory show the Clavipurin solution to exceed the declared potency, the latter result seems quite plausible. However, the firm does not claim that the activity of each batch of Clavipurin is controlled by pharmacologic assay, and the determinations quoted certainly indicate a lack of adequate standardization.

Therapeutic Usefulness.—The chief claims for Clavipurin are based on the clinical use which apparently dates from 1923. Most of the reports available to the Council's referee are enthusiastic, and several attempt to show that toxic results with Gynergen are comparatively common while these do not occur with Clavipurin. Since Clavipurin is not a pure alkaloid and is apparently quite variable in activity, the claimed lesser toxicity is very likely due to a lower potency. It is difficult to see how any other explanation can be adduced for this, since Gehe and Company claim precisely the same actions for Clavipurin as have been demonstrated for Gynergen. No evidence has been submitted that Clavipurin contains any substance that would tend to diminish the noxious effects, and the two active alkaloids, ergotamine and ergotoxine, have precisely the same toxicity according to competent and adequately confirmed observations in the literature. Gynergen solution-N N R contains approximately four times as much and Gynergen ampules-N N R about twice as much ergotamine tartrate as the ergotamine tartrate equivalent of the Clavipurin solution and ampules assayed for the A M A Chemical Laboratory.

The therapeutic results with Clavipurin appear to approximate those obtained with the standard fluidextract of ergot and with the accepted injectable preparations; however, so long as a product has a fair oxytocic potency, even if this is not uniform, it may be found clinically effective in a considerable number of cases, particularly (as is common practice) when it is used prophylactically. But in the literature submitted by the firm, the recommendations by several authors that the dosage be repeated indicates that Clavipurin is no more reliable in those cases with real uterine inertia than the assay data indicate.

Gehe and Ingram were informed that if acceptance of Clavipurin was desired, the firm would be required within a reasonable time to make the name and advertising acceptable to the Council,

to present complete data as required by the Council's rules, to standardize the product so as to make it acceptable to the A M A Chemical Laboratory, and to word the labels so as clearly to indicate the potency in terms of a standard preparation. This was transmitted to Gehe and Company, this firm replied in part that it would not be able to comply entirely with the Council's requirements.

Clavipurin was therefore declared unacceptable for New and Nonofficial Remedies because the composition is not fully revealed, because it is not adequately standardized as to potency, and because it is marketed under a nondescriptive proprietary name with unwarranted therapeutic claims.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

ROMAN MEAL

The Roman Meal Company at Tacoma, Wash., submitted to the Committee on Foods a product called "Roman Meal," prepared from coarsely ground whole wheat and rye with smaller proportions of wheat bran, and pulverized, partially defatted flax seed. The mixture is heated to 70 C to destroy any insect infestation, sifted, and automatically filled into cartons.

Analysis (submitted by manufacturer) —

	per cent		per cent
Moisture	8.3		
Ash	3.3		
Fat (ether extraction method)	3.2		
Protein (N X 6.25)	15.5		
Crude fiber	6.2		
Carbohydrates other than crude fiber (by difference)	63.5		
Phosphorus as P ₂ O ₅	1.690	(as P)	0.737
Sulphur as SO ₃	0.041	(as S)	0.016
Chlorine (Cl)	0.021		
Calcium as CaO	0.112	(as Ca)	0.080
Magnesium as MgO	0.545	(as Mg)	0.329

Aluminum as Al O ₂	0.0036	(as Al)	0.0019
Silicon as SiO ₂	0.020	(as Si)	0.009
Sodium as Na O	0.048	(as Na)	0.036
Potassium as K O	0.758	(as K)	0.629

Discussion of Label and Advertising.—The label and advertising make the following claims:

Roman Meal contains all the life giving properties of whole wheat and rye. It is now sterilized by subjection to a very high degree of heat. It is a perfectly balanced human food. It is a great aid to digestion and a positive relief to constipation. For over a century there has been a most urgent need for a simple and perfectly balanced human food that would prevent the development of abnormal or diseased conditions in the digestive tract. For a balanced food that shall offset the evils and deficiencies of the devalitized and over refined present day diet. By a balanced food we mean that it contains in proper proportions all of the elements which the body requires in maintaining a high degree of health and vitality. These four ingredients (of Roman Meal) are combined in such proportions as to make a perfectly balanced human ration for family use. Bear in mind that no one grain can be balanced. It requires combination. ROMAN MEAL is such a combination developed scientifically by a physician. It contains all the vital health giving mineral salts and vitamins. When a child is fed ROMAN MEAL it also receives proper amounts of soda, potash, lime, phosphorus, iron and other mineral matters to form bones, teeth, nerve and brain, give tonicity to muscles and hydrochloric acid for digestion and coloring matter to the blood. Eat Roman Meal for health. It aids the digestion of other foods.

Roman Meal is not a 'perfectly balanced food,' since it does not contain all the required nutritional elements in adequate proportions. It is not an aid to digestion' nor is it a 'positive relief to constipation.' The product contains considerable indigestible material which may aid in overcoming constipation due to insufficient bulk in the diet, it will not, however, correct pathologic constipation and may aggravate such a condition. It will not 'prevent the development of abnormal or diseased conditions in the digestive tract.' The food lacks a number of nutritional elements required for 'maintaining a high degree of health and vitality' and others are insufficient in quantity. The cereals and flax ingredients are not combined in any proportions known to have nutritional significance. "No one grain can be balanced nor can any combination of grains all the

grains have approximately the same nutritional limitations. Roman Meal was not developed "scientifically" by a physician. It is lacking in some of the vitamins and is only a fair source of others. The "mineral salts" as a whole are quite insufficient. Neither the minerals nor the vitamins are "health giving." "A child fed Roman Meal" does not receive "proper amounts" of the "minerals" to "form bones, teeth, nerve, brain, etc." The food is no more an aid "for health" than are other common foods.

The advertising goes on to claim

ROMAN MEAL cools the blood because of its alkaline Flaxose. Ordinary cereals heat the blood in summer because they are acid. Correct any over acid condition by the use of the naturally alkaline food Roman Meal. Lost Appetite will not trouble you during the hot spell if you counteract the excess acid of ordinary foods with the corrective alkaline properties of Roman Meal. In hot weather the over acid contents of meats, white flour and refined cereals produces lazy, drowsy, hate-yourself feelings. Roman Meal and other alkaline foods insure you more ambition and energy that you have ever known in summer. Roman Meal because of its Flaxose is the only alkaline cereal sold. It clears the skin.

Roman Meal does not 'cool the blood because of its alkaline flaxose' nor do 'ordinary cereals heat the blood in summer because they are acid.' The temperature of the blood of a healthy person is practically the same throughout all seasons. Roman Meal is not an 'alkaline food' as claimed, estimations from the mineral content indicate that it is slightly acid producing (estimated potential acidity [Sherman, H. C. *Chemistry of Food and Nutrition*, ed. 4, chapter XII, pp. 275-276] 0.4 cc normal acid). Therefore, Roman Meal will not correct any 'over-acid' condition. There is no authoritative information indicating that appetite is lost during the hot season because of 'the excess of acid of ordinary foods' nor that the acid producing foods such as meats and cereals produce 'lazy, drowsy, hate-yourself feelings.' Even if this were true, Roman Meal, because of the practically neutral value of its minerals, would be incapable of counteracting any acid effects of other foods. 'Roman Meal and other alkaline foods' are not known to insure 'more ambition and energy' in summer. The alkali requirements of the body are met by vegetables, fruit and milk. The aspersions directed at 'beef, white flour and refined cereals' because of their acid metabolic residues are unwarranted, these are wholesome foods and have a proper place in the diet as a whole. Roman Meal is not 'the only alkaline cereal sold.' Another cereal on the market is far more alkaline. In fact it is incorrect to designate Roman Meal as an 'alkaline cereal.' Roman Meal will not specifically 'clear the skin' any more than will many other common foods.

It is further alleged that

For generations bran and flaxseed as bran mash have been fed to stock as a conditioner and to increase the quantity and quality of milk. ROMAN MEAL because of its bran and flaxose content has a similar effect upon the human. It is a most efficient galactagogue. Flaxose is also added to compensate for the nutrition lost to any food by the addition of bran. Flaxose is three times as rich in protein as wheat, rye or oats. Thus by adding flaxose and the brown flour from the aleurone layer of the grain berry to the granulated whole wheat and rye we maintain in ROMAN MEAL proper balance between tissue building elements, saline matters and waste. Bran is added in ROMAN MEAL for bulk or waste only. It is pure cellulose therefore non digestible except in a limited way by action of the bacterial flora of the intestine and the saline constituents cannot be appropriated by the human.

But bran does cause catarrh of the colon used alone or used with refined grain products. To prevent this with ROMAN MEAL DEMULCENT FLAXOSE has been added which by its bland soothing action neutralizes the mechanical irritation caused by bran. Flax is included for its oil which soothes and lubricates as well as for the fibre bulk which it supplies. Flaxose is slightly hygroscopic and tends to prevent absorption of moisture from the fecal mass to dissolve fecal concretions. It also lubricates the intestinal wall. By both actions it lessens resistance to the intestinal flow and the increased propulsive force back of the fecal mass caused by bran. ROMAN MEAL is a most positive aid to the physician in the treatment of constipation and its attendant ills yet there will be no irritation to the sensitive alimentary mucosa as with the use of bran. Because it contains the dark flour from the aleurone layer of the grains ROMAN MEAL is rich in soluble salines. It thus differs materially from white flour, refined cereals and bran or any combination of these since flour and refined cereals contain but a trace or (of) salines and bran none (as far as the human is concerned). To add bran to any refined product does not restore balance. It adds bulk only, the important salines and vitamins are still absent—and these are even more important than bulk.

Roman Meal is not a galactagogue. The flax content does not 'compensate for the nutrition lost by the addition of bran.' The claim of 'proper balance between tissue building elements,

saline matters and waste' in Roman Meal is without meaning. Bran is not 'pure cellulose', it contains available nourishment. 'Bran used alone' or 'used with refined grain products' does not necessarily cause 'catarrh of the colon.' The addition of flax to Roman Meal cannot be expected to 'neutralize the mechanical irritation caused by the bran.' The claim 'flax was included for its oil' does not accord with the information provided by the manufacturer that the oil is removed from the flax before it is incorporated in Roman Meal. Since the oil is removed, the flax will not 'lubricate the intestinal wall' as claimed. The explanation of how Roman Meal acts on the intestine is largely fanciful. Roman Meal is not 'the most positive aid to the physician in the treatment of constipation and its attendant ills' nor is there assurance that 'there will be no irritation to the sensitive alimentary mucosa as with the use of bran.' The statements regarding the 'aleurone layer' ingredient and its contribution of 'soluble salines' are largely without meaning. The claim that bran provides no available 'salines available to humans' is incorrect. Contrary to claims bran also contributes vitamin B.

It is further stated that the ingredients of Roman Meal are

cut into little granules that the food may be porous to the digestive fluids. Crushed or rolled foods tend to become amorphous and are not porous to the digestive fluids and their enzymes. Thus ROMAN MEAL PROMOTES digestion. It is itself easily digested—it aids the digestion of other foods. It is rich in essential vitamins. While not so rich in fat soluble A vitamin ROMAN MEAL with the addition of cream, whole milk or cow butter is richer than any other cereal in this vital element and abundantly sufficient for every possible need. Cure Constipation and you cure all. Rheumatism, appendicitis, indigestion, stomach troubles, chronic headache, unsightly pimples and blotches, bad breath and scores of other ailments can be traced directly to constipation. ROMAN MEAL is indeed a simple and natural remedy for some of the most widespread and insidious ills to which mankind is subject. At the time when the body is in its formative stages ROMAN MEAL supplies the potash, lime, phosphorus, iron and other elements needed in laying the foundation of health that will carry the child through life. This is the period when the teeth are being formed. Deficiencies in diet result in weak tooth structure and it is a condition that cannot be corrected after the second teeth are formed. ROMAN MEAL if used regularly and consistently will give your child the start in life you owe him. Physicians prescribe ROMAN MEAL for children for brain and muscle workers for athletes for nursing and expectant mothers for the aged undernourished and anemic—for the sick and those who wish to maintain present good health.

Roman Meal is not porous to the digestive fluids' because it is cut into little granules' nor is it true by comparison that 'crushed or rolled foods' are not porous to the digestive fluids and their enzymes. The explanation of how Roman Meal 'promotes digestion' has apparent plausibility only. Roman Meal does not aid the digestion of other foods, a claim implying digestive action as possessed by digestive enzymes. It is not rich in essential vitamins. The claim that Roman Meal mixed with cream or butter 'is richer than any other cereal in vitamin A' is worded to trick the reader to understand Roman Meal is rich in vitamin A, whereas it is contributed mostly by the cream or butter. Not all ills are cured when constipation is cured. The various ills related cannot be attributed in all cases to constipation. Roman Meal is not a remedy in any sense for most widespread and insidious ills. It does not supply the various chemical elements stated in the quantity needed to lay the foundation of health that will carry the child through life. Roman Meal is not specifically helpful for nourishment of teeth to the contrary foods such as Roman Meal lend to poor tooth development. Physicians do not specially prescribe Roman Meal as stated.

It is claimed that

ROMAN MEAL was invented by a physician. The cereal manufacturer's idea has been to refine away all the coarse and darker parts of grains. Thus has removed the real food value, those parts which build muscle, bone, brain, nerve, keep the blood from becoming acid. This invites disease. It is common knowledge that rheumatism is caused by acid blood yet this is only one of many diseases caused by absence from the blood of the alkaline salts obtained largely from the dark parts of grains. Roman Meal retains all the alkaline salts. This makes for healthy blood. Wheat is only about three quarters as nourishing as rye and only about one third as nourishing as flax. Roman Meal is largely made up of rye and flax. It is therefore the most nourishing cereal ever sold. It is the most perfect food ever devised. It is non-starchy and does not ferment. It makes bone, muscle and nerve better than meat. Ordinary cakes and pastry are most injurious to the growing child but ginger bread, cookies, muffins, gems and puddings as well as mush made from ROMAN MEAL make ideal lunches between meals for the child.

Contrary to the claims, refined cereals have definite food values, "coarse and darker parts of the grains do not especially 'build muscle, bone, brain, nerve,' nor do they 'keep the blood from becoming acid'." Whole grain cereals have broader nutritional values than refined cereals but refined cereals have a proper place in a satisfactory diet. Rheumatism is not 'caused by acid blood' nor are 'many diseases' caused by absence from the blood of the "alkaline salts obtained largely from the darker parts of the grains." Roman Meal does not necessarily "make for healthy blood." It has never been demonstrated that "wheat is only about three-quarters as nourishing as rye, and only about one-third as nourishing as flax." Roman Meal is not 'the most nourishing cereal ever sold.' In fact, some other cereals provide much broader nutritional values. Roman Meal is far from being the 'most perfect food ever devised.' It is not "non-starchy," and it may "ferment." It does not "make bone better than meat" and Roman Meal lunches are not "ideal for children."

The advertising is an elaborate attempt to transform Roman Meal into a medicinal food with fictitious health properties, it has all the appearances of studied deception to exploit the gullible and the uninformed in dietetics, nutrition and physiology. It grossly misrepresents the product is replete with misinformation, and promotes self diagnosis and self treatment by the sick with possible disastrous results. It is a corruption of the purpose of advertising to the trade and to the public. Insidiously false advertising of this character tends to degrade food advertising to subtle trickery.

Roman Meal because of its grossly deceptive advertising, will not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

MCCORMICK'S BEE BRAND WHITE PEPPER

Manufacturer—McCormick and Company, Inc., Baltimore

Description—Ground white pepper (berry of *Piper nigrum* L. with the epicarp removed)

Manufacture—White pepper is prepared from black pepper berries by removal of the outer black epicarp. The pepper berries almost completely mature on the vine. After picking they are allowed to stand for several days and are bruised and washed to remove stems and to separate the pulpy epicarp. The inner portion of the berry is dried on mats, exported to the company's picking plant, cleaned, ground and packed in tins.

Analysis (submitted by manufacturer) —

	per cent
Moisture	11.9
Total ash	1.4
Acid insoluble ash	0.1
Volatile ether extract	1.0
Nonvolatile ether extract	7.3
Total nitrogen	2.0
Piperin nitrogen	0.4
Piperin	6.2
Protein (N x 6.25)	1.6
Starch (diastase method)	10.2
Crude fiber	55.2
Carbohydrates other than crude fiber (by difference)	3.9
	64.3

Claims of Manufacturer—Conforms with the respective United States Department of Agriculture definition and standard.

AMERICAN BRAND EVAPORATED MILK UNSWEETENED STERILIZED

Packer—Oatman Condensed Milk Company, Dundee, Ill.

Description—Canned unsweetened sterilized evaporated milk the same as Oatman's Brand Evaporated Milk (THE JOURNAL, April 16, 1932, p. 1376).

KRASDALE BRAND CALIFORNIA WHITE MEAT TUNA

(PACKED IN HIGH GRADE SALAD OIL)

Packer—Hovden Food Products Corporation, Monterey, Calif.
Distributor—A. Krasne, New York.

Description—Cooked light meat of Yellowfin Tuna with added salt, refined cottonseed oil and sour pickle, the same as Portola Brand California Tuna (THE JOURNAL, May 28, 1932, p. 1885).

EVANS' E-Z-BAKE FLOUR (BLEACHED)

Manufacturer—Acme-Evans Company, Indianapolis

Description—An 'all purpose' short-patent flour milled from hard and soft wheats, bleached.

Manufacture—Selected soft and hard wheats are cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-seventh ounce per 196 pounds).

Claims of Manufacturer—Intended for all baking purposes.

CLAPP'S ORIGINAL PUREE OF BEETS

(ADDED SALT)

Manufacturer—Harold H. Clapp, Inc., Rochester, N. Y.

Description—Strained cooked beets. The method of preparation is efficient for retention in high degree of the natural vitamins and minerals. A small amount of salt is added.

Manufacture—Purchased canned beets are strained in an atmosphere of steam. The subsequent treatment is essentially that described for Clapp's Original Baby Soup (THE JOURNAL, Aug. 19, 1933, p. 605).

The purchased canned beets are prepared, canned and processed as described for the purchased canned carrots (THE JOURNAL, June 24, 1933, p. 2011).

Analysis (submitted by manufacturer) —

	per cent
Moisture	90.5
Total solids	9.5
Ash	0.4
Salt (NaCl)	0.3
Fat (ether extract)	0.2
Protein (N x 6.25)	0.9
Crude fiber	2.4
Carbohydrates other than crude fiber (by difference)	5.6

Calories—0.3 per gram, 9 per ounce.

Vitamins and Claims of Manufacturer—See Clapp's Original Baby Soup (THE JOURNAL, June 24, 1933, p. 2011).

CRESKA HYGEIA FIGS

(NATURAL SUN DRIED UNSULPHURED)

Importer and Distributor—Creska Company, Inc., New York.

Description—Unsulphured cleaned dried Creska Choicest Smyrna Locoum Figs.

Manufacture—The figs are the same as those used for Creska Choicest Smyrna Locoum Figs. Not sulphured (THE JOURNAL, Nov. 19, 1932, p. 1780). Cleaned, dried figs are packed in waxed paper in cartons.

SNOW DROP FLOUR (BLEACHED)

SILVER SPRAY BEST PASTRY FLOUR (BLEACHED)

GLOBE PASTRY FLOUR (BLEACHED)

Manufacturer—Federal Mill Inc., Lockport, N. Y.

Description—Bagged soft winter wheat "straight" flour, bleached.

Manufacture—Selected soft white winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. The flour streams are blended and bleached with nitrogen trichloride (one-fourteenth ounce per 196 pounds) and with nitrogen oxide.

Claims of Manufacturer—For baking cakes, biscuits and pastry.

PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The present list of physicians specializing in pathology and clinical pathology is the outgrowth of the survey of clinical laboratories that was begun in 1924. At that time the House of Delegates instructed the Council to ascertain how best to regulate the clinical laboratory situation. A committee of pathologists, including members of the American Society of Clinical Pathologists and the American Association of Pathologists and Bacteriologists, was appointed to assist the Council in securing information in regard to commercial clinical laboratories.

The original request for some regulation regarding clinical laboratories came from the clinical pathologists in 1923, the two societies mentioned having worked independently for some time toward a solution of the problem. Some means of eliminating lay specialists in this field was sought. It was held improper for any person not qualified educationally and legally to assume the responsibility of making a diagnosis or prognosis, or of acting as a consultant with regard to disease in the human body. Where the law does not restrict diagnosis and the interpretation of laboratory observations to qualified medical practitioners, all other means available should be used to protect the patient against the incompetence of the lay specialist and the nonmedical clinical laboratory.

For seven years the Council, with the assistance of the committee of pathologists, approved clinical laboratories according to a minimum standard, the principal emphasis being on the qualifications of the pathologist. The list of approved laboratories was published periodically, and physicians were urged through the publications of the Council to patronize only such clinical laboratories as were under the direction of physician pathologists. In 1931 the listing of clinical laboratories was changed and has since been a list of pathologists and clinical pathologists, on the basis of their education, training and experience. It was also expanded to include teachers and those employed in hospital, research or governmental laboratories. The present list of physicians specializing in pathology and clinical pathology contains 704 names. Applications for recognition are being considered regularly. Thus it may be said that the clinical laboratories now recognized by the Council are those which are under the direction of the pathologists listed.

The progress made in this endeavor to distinguish the medical from the nonmedical clinical laboratories has been in direct proportion to the cooperation extended by the profession. Many physicians in the past, not appreciating fully the importance of medical supervision over their work, had patronized lay laboratories. The work of the Council has been responsible to some extent for the decrease in the use of lay clinical laboratories by the medical profession. The patient should be given the benefit of the most accurate analysis with regard to the source, nature and progress of disease. In order that this may be assured, physicians should have their work carried out in laboratories under the supervision of capable physician-pathologists.

In 1928 the Section on Radiology requested the Council to carry out a similar work for radiologists. A list of physicians specializing in radiology is also maintained by the Council in the same manner as the list for pathologists and clinical pathologists. At the present time, 1,230 radiologists have been admitted to the Council's list.

METHOD OF PREPARATION

The method of preparing a list of physicians specializing in pathology and clinical pathology is as follows:

- 1 Physicians expressing a desire to be considered for listing receive a form on which they submit data regarding their medical graduation, internship, licensure, postgraduate work, experience, special society affiliation, hospital appointments, publications and other pertinent data.

- 2 The data submitted are verified by comparison with the biographic files of the American Medical Association, by the official reports of their medical college of graduation, and by reports from hospitals or medical institutions in which the candidates may have served. Former teachers, preceptors and associates are often consulted. The official reports received from boards of medical education and licensure are checked, and membership in special societies is confirmed. Records in government service or other employ are used.

- 3 The questionnaires are then reviewed in the office of the Council and those which, by their own statements, clearly do not fulfill the essentials are eliminated. The names of applicants with their qualifications are sent to the members of the advisory committee. This advisory body numbers about 175 specialists, who were selected from among the pathologists who are best qualified to act in that capacity, nominations being made mainly by pathologists.

- 4 Advice regarding the eligibility of candidates is obtained from individual members of the advisory committee and each is asked to submit his opinion or recommendation independently of others. Recommendations regarding each candidate are, as a rule, secured from several advisers averaging from three to six. In the light of all data thus far obtained, the applications are then taken up by the Council on Medical Education and Hospitals at its next quarterly meeting.

The place of the Council on Medical Education and Hospitals in this work is that of an impartial, fact-finding, classifying body. The expense is borne entirely by the American Medical Association. The only motive is the substantial betterment of pathologic service.

BIBLIOGRAPHY

The initial steps, beginning with the authorization of the movement by the House of Delegates of the American Medical Association at the annual session in San Francisco in 1923, are given in *THE JOURNAL*, April 3, 1926. That article contains the names of the members of the joint committee and gives a detailed account of the work of the committee and the Council on Medical

Education and Hospitals during the years 1923, 1924 and 1925. It contains a copy of the original questionnaire and the compilation of statistics on clinical laboratories gathered from all states of the Union by means of that questionnaire. Of special importance are the principles stated by the joint committee at that time—important because most of them still hold good, yet some of them would hardly be regarded as pertinent at the present time. The first provisional list was published in the report just referred to. Subsequent developments in the evolution of the list, and particularly the changes in the list itself, are reflected in the following references.

The second publication of the list appeared in *THE JOURNAL*, March 12, 1927, and contained 145 names, the list was next published in the Tenth Edition of the American Medical Directory in May, 1927, and contained 145 names, in *THE JOURNAL*, March 24, 1928, 160 names, March 30, 1929, 174 names, in the Eleventh Edition of the American Medical Directory, July, 1929, 175 names, in *THE JOURNAL*, March 29, 1930, 178 names, May 23, 1931, 183 names, and in the Twelfth Edition of the American Medical Directory, June, 1931, 183 names, in *THE JOURNAL*, Oct. 22, 1932, 538 names.

The following list in this issue contains 704 names

ESSENTIALS FOR THE LISTING OF PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

Admission to the list is open to all physician-pathologists engaged in pathologic work in accordance with the "Essentials," whether connected with a hospital or not. The work of compiling a list of qualified pathologists according to these "Essentials" is done by the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago.

Definition—A physician holding himself out as a specialist in pathology may be defined as follows: One who is a graduate in medicine having had satisfactory training and experience in pathology, chemistry, bacteriology or other allied subjects for at least three years subsequent to graduation, who is in good standing and has been duly licensed to practice medicine.

Qualifications—(a) The pathologist shall be on a full or part time basis with a laboratory for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, nature, source and progress of disease in the human body. He should devote the major part of his time to work in this field.

(b) Pathology should be practiced on the same scientific and ethical basis whether in the hospital or in a detached laboratory. The work represents the practice of medicine as in other specialties.

The pathologist may make diagnoses only when he is a licensed graduate of medicine, has had satisfactory training and experience in pathology for at least three years subsequent to graduation from medical college, is reasonably familiar with the manifestations of disease and is competent to make reliable reports.

(c) **Assistant**—The pathologist may have a corps of qualified assistants and technicians, responsible to him, and for whom he is responsible, to carry out promptly, intelligently and accurately the several kinds of service

the laboratory offers. All their reports, not only of tissues but also of all bacteriologic, hematologic, biochemical, serologic and pathologic data, should be made to the pathologist.

Scope—A general pathologic laboratory should be prepared to render the following services:

(a) **Hematologic**—Blood counts, blood groupings and coagulation tests, and tests for blood parasites in general.

(b) **Biochemical**—Qualitative and quantitative analyses of urine, blood, gastric contents, body fluids, feces, intestinal contents and cerebrospinal fluids, renal and hepatic function tests and basal metabolism.

(c) **Bacteriologic**—Bacteriologic diagnoses, preparation of vaccines and blood and body fluid cultures.

(d) **Serologic**—Serologic diagnoses, agglutination, complement fixation, or precipitin and lysis tests.

(e) **Pathologic**—Preparation of paraffin, celloidin or frozen sections, microscopic and gross pathologic specimens and necropsies.

(f) **Parasitologic**—Protozoal and zoological diagnoses.

(g) **Metabolic**—Disorders of metabolism.

(h) **Cardiologic**—Disorders of the heart.

It is of course not expected that the candidate shall be prepared to render all the services mentioned, since the work must necessarily be diversified in larger laboratories and in smaller laboratories it is not always practical to have equipment and setups that would be used only occasionally. Since many pathologists limit their work to one branch of the specialty, referring certain items, far more efficiency is to be expected.

Reports—Reports should be made solely to the physician in charge of the patient and should be signed by the pathologist. All blanks and reports should have the name of the director printed on them and, if of a diagnostic or prognostic character, the name of the staff physician also.

Records—Full records of all examinations made by the pathologist, suitably indexed and filed, are essential. Every specimen analyzed in the laboratory should be given a serial number, which should follow that specimen in the records and reports. When the laboratory report concerns a hospital patient, an exact transcript of the laboratory record should be appended to the hospital case record. Each specimen submitted to the laboratory should be accompanied by pertinent clinical data.

Library—The laboratory should be provided with, or have convenient access to, a library including current scientific books and journals on all the various subjects required in its work.

Fees—There should be no dividing of fees or rebating between the laboratory or its pathologist and any physician, corporate body or group.

Publicity—Publicity should be in professional good taste and be limited to statements of fact, as the name, address and telephone number of the laboratory, names and titles of the pathologist and other active responsible personnel, fields of work covered, office hours, directions for sending specimens, and the like, and should not contain misleading statements or claims of unusual superiority. It should not advocate medical fads nor lay undue stress on the importance of laboratory observations.

Only the names of those rendering regular service to the laboratory should appear on letterheads, or any

other form of publicity, as being connected with the laboratory

Advertising matter should be directed only to physicians either through bulletins or through recognized

technical journals, and never to the nonprofessional public, as, for example, by announcements in popular journals and periodicals, circulars, pamphlets, telephone lists or other means

PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

The following list contains the names of 704 physicians specializing in pathology, laboratory diagnosis or clinical pathology, who returned the questionnaire, who were found to meet the Essentials" and were recommended by the Council's advisers. Those engaged in teaching, research and other activities are admitted as well as those in active practice. For the list of physicians specializing in pathology in government service, see page 1237

VOLATILE POISONS IN THE AMERICAN HOME

Modern chemical industry in its many branches contributes greatly to the comforts and even luxuries of life. At the same time it introduces new hazards to health and even to life. While these hazards arise primarily in industry and can there be minimized by adequate precautions, safety supervision and compensation for injuries, they now invade nearly every American home, and in the home there is little protection and no compensation for injuries. New solvents for cleaning purposes, new forms of paint, new refrigerants for gas and electrical refrigerators, new drugs, new textiles to imitate silk and other fabrics, and new materials for a wide variety of other uses are already generally introduced. More are appearing constantly to improve or replace the materials formerly used. Some of these materials appear to be entirely harmless, others are distinctly poisonous. This defect, however, should not prevent their use for proper purposes with adequate precautions. Their advantages must be retained. Knowledge must serve as a protection from their perils.

Among the substances that have marked toxic qualities, various volatile liquids are especially important both in their convenience for household use and in their risks to health. The fatalities that resulted from methyl chloride poisoning in Chicago apartment houses, where this gas escaped from refrigerators, are still fresh in the public mind. Benzene is not only a factory hazard but when used in asphalt paint on hot metal in an unventilated place may induce illness or death. Methanol in varnish may cause blindness. The only protection for the public against this risk at present is a gentleman's agreement among the more public spirited manufacturers not to yield to the temptation of cheapening production by using methanol in varnish. A nationwide disaster with a probability of hundreds of poisonings was barely averted a few years ago when the sale to the public at gasoline filling stations of concentrated tetra-ethyl lead was replaced by the relatively

safe ethyl gas, in which the lead is already mixed before distribution. In regard to refrigerators the choice of safety or danger seems to depend less on what particular refrigerant is used than on the quantity. In single unit installations the amount is small. In multiple installations, particularly in apartment houses the amount is large, and the whole of it may escape into a single apartment when a leak occurs. One of these refrigerants the new dichlorodifluoromethane, is practically nontoxic,¹ yet when stored in large amounts in the basement to supply many refrigerators from a single tank and compressor it might produce a veritable war gas wave in case of fire to overwhelm the firemen. Safety seems now to require that such substances be used only in single units of household size.

One of the most widely used volatile liquids is carbon tetrachloride. For purposes of dry cleaning this liquid has the great advantage over many other solvents of grease in that it is noninflammable. Fire risks, and therefore fire insurance rates, for plants using carbon tetrachloride are much less than when such inflammable liquids as naphtha or gasoline are used. As "carbona," carbon tetrachloride goes into the home chiefly to remove grease spots. Its use has aided to diminish the injuries and deaths from burns that formerly resulted from the household use of such inflammable cleaning fluids as naphtha. The public is, however generally quite unaware that carbon tetrachloride is a powerful anesthetic and nearly as toxic as chloroform. Butsch² has recently reported a case in which a man who was employed to clean telephones with this substance has apparently suffered irreparable damage to the liver. Cases have also been reported from Switzerland of illness from a floor wax liquefied with carbon tetrachloride and used in school rooms.⁴ There have been many cases of partial poisoning from nearly every use of this substance by persons who appreciated its advantages but were unaware of the precautions necessary against its dangers. With reasonable care, most of these uses would be quite safe, the danger results from ignorance and lack of warning regarding the poisonous properties of carbon tetrachloride and from the fact that the substance is generally sold for household use not under its scientific name but under such trade names as "carbona" and "pyrene."

When carbon tetrachloride is used to extinguish fires in closed spaces, the results may be disastrous. The New York Times for July 7, 1922, reported a fire in the subway on which "pyrene" was used with the result that 150 persons were overcome by the fumes. In adjoining columns of the Times a statement from the

2 Report on Dichlorodifluoromethane National Board of Fire Underwriters Oct 10 1931 Williams E T and Kenlon J A Brief Before the Fire Department of the City of New York Board of Hazardous Trades in the Matter of Freon Dichlorodifluoromethane.

3 Butsch W L Cirrhosis of the Liver Caused by Carbon Tetrachloride J A M A 99 728 (Aug 27) 1932.

4 Hengeler A Serious Poisoning with Carbon Tetrachloride Schweiz med Wchnschr 61 223 (March 7) 1931 abstr J A M A 96 1917 (May 30) 1931.

Chemical Warfare Service of the United States Army set forth the well known fact that carbon tetrachloride is like chloroform in that when the liquid is sprayed on a fire, or its vapor is mixed with flame, it produces phosgene, one of the most deadly of war gases. From the subway fire no deaths resulted, but in the United States Navy at the Portsmouth Navy Yard in 1919 two men died from the fumes produced when the clothing of one caught fire and was extinguished with "pyrene."

Experience has demonstrated that carbon tetrachloride has excellent fire-extinguishing properties. "Pyrene" in the small fire extinguishers often carried in automobiles has saved many a car from destruction and its owner from injury by explosion of gasoline vapor. In the open air the danger from poisoning is small, but as the result of an investigation of this subject in the Bureau of Mines⁵ the conclusion was reached that carbon tetrachloride should not be used for this purpose in confined spaces. Accordingly, under the influence of that bureau the use of carbon tetrachloride in mines has been generally stopped. Unfortunately the American home is not so well protected, as carbon tetrachloride fire extinguishers are sold to the public for use in homes with no statement on the label of the containers as to the conditions under which their use is dangerous.

Of such dangers from well known toxic substances that go into the modern American home it would be easy to make an extensive list. But even more important is the risk from new substances the toxic qualities of which are as yet undefined by experience or investigation. At the last session of Congress a bill⁶ was introduced in the United States Senate to require truthful labeling of volatile substances sold through interstate trade for household use. After a preliminary hearing before a committee of the Senate this bill was referred to the surgeon general of the Public Health Service for study, possibly for enlargement into a general poisons bill, and then for report back to the committee of the Senate. It is needed in regard not only to carbon tetrachloride and other substances of known toxicology but also to forestall the poisoning of the people in their homes by new substances of unknown toxicology. It should provide for investigation under government auspices of the toxic hazards of new substances before they are sold under some misleading trade name to an uninformed and as yet unprotected public.

PRESBYOPIA AND THE DURATION OF LIFE

Presbyopia has long been recognized as a condition that attacks human beings beyond middle age and gradually increases until the age of 60 years, after which it is likely to remain stationary. This recession of near point for vision is considered a normal process in the life cycle of the tissues of the eye. It is apparently associated with a change in the tissue of the lens in the direction of increased hardness and lessened elasticity. Because of this inability of the lens to stretch or relax in response to the demand for accommodation, the ability to see printed matter or objects held close to the eye is decreased.

Not long ago Steinhaus¹ developed the conception that a definite relationship exists between aging of the lens of the eye and aging of the body in general. He pointed out that Kronfeld had previously demonstrated that the energy requirements of the lens are the same as those of the erythrocytes. In spite of the peculiarities of the tissues of the eye, they seem to be governed by the same laws that control other tissues. The lens of the eye of a child is so elastic that it can readily assume any shape necessary for accommodation to vision at various distances. In near vision, extreme curving is necessary. As the human being becomes older, the tissues tend to lose their elasticity, as is visible in the case not only of the lens of the eye but also of the skin. The gradual hardening process that takes place with increasing age is a general process affecting all the tissues. When it affects the lens of the eye, the power of accommodation is impaired so that the near point for vision gradually moves farther away from the eye. Steinhaus was convinced that aging of the lens and of the body tissues generally continued in a parallel manner, and that by this means the degree of presbyopia found in any individual might be taken as an indication of life expectancy.

After propounding this theory, Steinhaus studied the records of the Leipzig clinic for diseases of the eye for the period from 1880 to 1908, and also for the years 1929 and 1930. For each year of persons over 40 years of age a presbyopic average was determined, and tabular statements were developed indicating the presbyopic averages expressed in diopters. In comparing with this average the degree of presbyopia in the different patients, he detected persons in whom the presbyopia was less than average and above the average. The tables seem to show that there is a relationship between the degree of presbyopia and the life expectancy. In persons in whom the presbyopia is less than average, life expectancy is much greater than in those in whom presbyopia is above the average. In persons between the ages of 40 and 50 the difference is as much as ten years in favor of the persons with a less than

⁶ Senate bill 1931. Seventy Second Congress first session introduced by Senator Bingham and referred to the Committee on Agriculture and Forestry the act to be cited as the Federal Volatile Poison Act. Volatile Poisons. Hearing before the Committee on Agriculture and Forestry United States Senate on S. 1931. A Bill to Regulate Interstate and Foreign Commerce in Poisonous Volatile Substances. Intended for Household Consumption. April 19 1922. Washington Government Printing Office 1932.

¹ Steinhaus Heinz. Relation of Presbyopia and Duration of Life with Consideration of Causes of Death. Arch. f. Augenheilk. 105 731 (Nov.) 1932.

average presbyopia. A sifting of the material according to causes of death showed a more noticeable relationship between presbyopia and duration of life in persons who died a natural death, for in these cases the aging process is the most important cause of death. As the sclerosis of the eye lens is an indicator for the advancement of the aging process in the vital organs, it is thus also an indicator of the life expectancy. From this Steinhaus concludes that the determination of presbyopia may be of value in the examination of applicants for life insurance. A classification of the material according to the sexes revealed that the presbyopic averages are the same in men and in women. The fact that women, as is generally known, have a higher life expectancy is not due to a lesser degree of aging but to other causes, such as their mode of life, which is generally quieter than that of men. The presbyopic averages of the material of 1929-1930 were found higher than those of the years 1880-1908, but the author thinks that this is due to changes in the method of prescription of glasses rather than in actual changes. For differences in the process of aging between urban and rural populations, between the different social classes and between different races there are some indications, but these were not definite.

Most of our means of determining changes in the elasticity of the blood vessels and of various other tissues of the body are clinical methods seldom permitting exact measurement. On the other hand, the methods of refraction that determine with remarkable exactness the relative elasticity of the lens may be considered a highly scientific and accurate means of measurement. If, therefore, the concept of Steinhaus is more definitely established by the accumulation of a considerable number of observations on large numbers of people, a simple means for aiding in determining life expectancy will be easily available.

Current Comment

LYMPHATIC BLOCKADE

The tendency of staphylococci to remain localized in infected areas and the usual spread of streptococci to surrounding tissues are well known clinical phenomena. Superficially, this suggests a relatively low virulence or toxicity for the staphylococcus, and a relatively high pathogenicity or invasive potential for the streptococcus. A quite different interpretation, however, is suggested by Menkin¹ of Harvard Medical School, who emphasizes differences in local tissue drainage. The Harvard investigator found that aleuronat and certain other injected irritants are usually fixed in local tissues, largely as a result of a mechanical blockade of the regional lymphatics. This blockade is caused by intraluminal plasma coagulation and the later formation of leukocytic plugs. Trypan blue

injected into the inflamed area is retained in the local tissues, while similar injections are rapidly drained from noninflamed control areas. Applying the same local drainage test to bacterial infections, he found in rabbits an effective regional lymphatic blockade within one hour after the subcutaneous injection of staphylococci. An equally effective regional blockade required at least forty-five hours with streptococci. Pneumococci occupied an intermediary position, effective regional blockade being established in about six hours. "Inasmuch as staphylococci, pneumococci, and streptococci spread from the site of cutaneous inoculation primarily through lymphatic channels," he says, "the difference in rapidity with which mechanical obstruction is set up in the areas inflamed by them will help to explain the differing invasive abilities of these pyogenic organisms."

THE WHITE BLOOD CELL COUNT

Scarcely a day passes in the lives of many physicians when they are not concerned with the "white blood cell count" of some patient. To base a diagnosis of disease on an aberration in the number of circulating leukocytes calls for dependable knowledge of normal conditions. Without this, rational judgments as to what constitute abnormal changes or pathologic signs cannot be formed. Just as the clinician takes into account the diurnal variations in body temperature when he uses the clinical thermometer, so the "rhythms" in white cell counts need to be considered if they are, indeed, physiologic realities. An "afternoon rise" has been described as an actual phenomenon, in contrast to some other variations now attributed to errors in technique. Reference was made some time ago in *THE JOURNAL*¹ to the conclusion that so-called digestive leukocytosis has been wrongly ascribed to alimentary causes. It was argued that physical or even mental exertion is the most conspicuous reason for these normal fluctuations in the increased numbers of white blood cells so often recorded after meals. Garrey² of Vanderbilt University at Nashville, who championed these views, contended that a count above 7,000 per cubic millimeter is evidence of mental or physical unrest and that all "basal counts" lie between the limits 5,000 and 7,000. Extensive investigations³ at the Washington Square College of New York University do not support this view but tend to indicate that mild activity has no constant effect on the count, although, as is well known, severe exercise may cause the number of leukocytes to rise to three or four times the normal figure. In persons at rest counts between 4,700 and 11,500 were obtained while the counts during activity varied between 3,500 and 11,500. The counts taken during activity were not uniformly higher than those obtained during complete rest, and just as frequently the two counts were substantially the same, or the count during activity was lower than that during complete rest.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8 55 to 9 o'clock central standard time, over Station WBBM (770 kilocycles, or 389 4 meters)

The subjects for the week are as follows

October 17 How to Care for the Heart
October 19 Parents Responsibility in Disease Control

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM

The subject for the week is as follows

October 21 The Battle of the Children

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

CALIFORNIA

Personal—Dr John J Miller Jr, who has been conducting research in whooping cough at the Statens Serum Institut Copenhagen, for the past year, will collaborate with Dr Albert P Krueger in a similar investigation at the University of California, Berkeley

Changes at University of California—Dr Herman M Adler, professor of psychiatry, University of California Medical School, San Francisco, will have the additional title of lecturer in jurisprudence during the present academic year New appointments include those of Drs Charles Weiss as associate professor of research medicine at the Hooper Foundation for Medical Research and Paul A Giebe as assistant clinical professor of neuropsychiatry in the medical school

Outbreaks of Food Poisoning—Four outbreaks of food poisoning were recorded during July according to the *Weekly Bulletin* of the California Department of Public Health One involved chocolate eclairs and another custard-filled cake Staphylococcal infection was responsible for both of these outbreaks In both of them the product had been shipped to another town from the locality where it was manufactured Eighteen cases of food poisoning occurred in a camp of young women The fourth outbreak involved nine cases in a labor camp Because of a shortage of ice in extremely hot weather, foodstuffs were not cared for properly In both these outbreaks the suspected food products were not available for laboratory study and the exact cause could not be determined

COLORADO

Dr Hall Honored—Dr Josiah N Hall Denver was given a dinner September 18 by the Medical Society of the County of Denver, in recognition of his completion of fifty years in the practice of medicine in Colorado There were 210 guests and the evening was concluded with the unveiling of a portrait of Dr Hall The portrait by Waldo Love, will be placed in the society's library Dr Robert Levy was toastmaster The speakers included Drs Hubert Work, former secretary of the interior Leonard Freeman John W Ames and George M Blickensderfer Dr Hall who is emeritus professor of medicine University of Colorado School of Medicine was president of the Colorado State Board of Medical Examiners in 1891 the state board of health in 1903-1904 the American Therapeutic Society in 1916-1917 and the Colorado State Medical Society in 1900 He was mayor of Sterling in 1888-1889 In addition to articles on diseases of the heart and lungs he is the author of *Borderline Diseases* and the section on gunshot wounds burns and scalds in Peterson and Haines' Text Book of Legal Medicine and Toxicology He served as a member of the Judicial Council of the American Medical Association from June 1921 to June 1931 was a member of the House of Delegates in 1903 and was again appointed in 1906 serving until 1908 and from 1919 to 1921

DELAWARE

Society News—At a meeting of the New Castle County Medical Society, Wilmington, September 19, Dr Edward S Dillon, Philadelphia, spoke on the reduction of mortality in diabetes Dr Thomas B Holloway Philadelphia, addressed the society, October 17, on exophthalmos and its significance

State Medical Election—At the annual meeting of the Medical Society of Delaware, September 26, Dr Joseph S McDaniel, Dover was elected president, Dr William H Speer, Wilmington, secretary, and Dr Alfred L Heck, Wilmington, treasurer, all to take office in January The next annual session will be held in Dover, Oct 9-10, 1934

DISTRICT OF COLUMBIA

Tumor Registry—A committee has been appointed by Dr Prentiss Willson, president Medical Society of the District of Columbia, to supervise a tumor registry recently established in the society's building Maintenance of the registry was authorized by the society, May 3 Dr Janvier W Lindsay was named chairman to serve three years Other members are the following physicians

Walter J Freeman three years	Claude Moore two years
Matthew White Perry three years	Frank J Eichenlaub one year
James A Cahill Jr two years	Vincent J Dardinski one year
Edmund Horgan, two years	Harrison H Leffler one year

GEORGIA

Society News—Speakers before the Ninth District Medical Society September 20, were Drs Grady N Coker, Canton, on *Rare Findings in the Surgical Abdomen*, and Daniel C Elkin, Atlanta, *Treatment of Aneurysm*—Dr Horace G Huey, Homerville, presented case reports before the Ware County Medical Society, September 6, on pernicious anemia, epithelioma of the forehead, aortic dilatation and pyloric stenosis

Department of Bacteriology Established—A department of bacteriology has been established at the University of Georgia Medical Department According to the *Journal of the Medical Association of Georgia*, the faculty of the department will include James A Kennedy, Ph D, University of Rochester (N Y) School of Medicine, Dr Ferdinand C Lee, Johns Hopkins Hospital Baltimore, James O Pinkston, Harvard Medical School, Boston, and Dr Marion S Dooley, Syracuse University College of Medicine, Syracuse, N Y

IDAHO

State Medical Election—At the annual meeting of the Idaho State Medical Association in Twin Falls, September 18-19, Dr Charles R Scott, Twin Falls was named president-elect, to take office January 1 Dr John S Springer, Boise, will assume the presidency, January 1 The next annual session will be held in Lewiston in 1934 The following scientific program was presented at the meeting

Dr Alan L Hart Tacoma Wash	Tuberculin Testing and X Raying of Chests of School Children
Dr Harry E Kleinschmidt New York	Finding Tuberculosis in School Children
Dr George W Pierce San Francisco	Practical Application of Reconstruction Surgery and Rational Treatment of Cleft Lip and Cleft Palate
Dr Claude F Dixon Rochester Minn	Gout and Surgery of the Colon
Dr Dean Lewis Baltimore	President American Medical Association Tumors of the Breast and Fractures and Associated Injuries
Dr Martin B Tinker Ithaca N Y	Gout, Diagnosis and Permanence of Cure
Dr Alfred W Adson Rochester Minn	Value of Sympathectomy in the Treatment of Cord Bladder and Hirschsprung's Disease
Dr Harlow Brooks New York	The Heart in Influenza
Dr Platt W Covington Salt Lake City	field representative Rockefeller Foundation State Board of Health Organization
Dr Alison R Kilgore San Francisco	Breast Cancer Acceptable and Debatable Procedures A State Medical Society Cancer Organization

ILLINOIS

County Society Programs on Infectious Diseases—The Illinois State Health Department will institute a series of scientific programs for county medical societies at a meeting of the Fulton County Medical Society in Canton, October 18, as part of a campaign against epidemic diseases Four illustrated lectures covering encephalitis, infantile paralysis, influenza pneumonia, diphtheria, scarlet fever and other epidemic diseases will be presented at each meeting by staff members of the health department Lectures have also been scheduled for meetings in Charleston, Champaign, Danville, Marion, East St Louis and Quincy

Chicago

Special Annual Lectures—Dr Hugh H Young, clinical professor of urology, Johns Hopkins University School of Medicine, Baltimore, will present the fifth annual William T Belfield Lecture before the Chicago Urological Society at the Palmer House, October 18. His subject will be "Diagnosis and Treatment of Prostatic Obstruction." A dinner will be held in honor of Dr Young preceding the meeting, and his friends and those interested in urology are cordially invited.—Dr George Minot, professor of medicine, Harvard Medical School, Boston, will deliver the first Jessie Horton Koessler Lecture of the Institute of Medicine of Chicago, October 23, on "Anemia, Etiology and Treatment." The meeting will be held jointly with the Chicago Society of Internal Medicine at the Chicago Woman's Club.—Dr Alfred Blalock, associate professor of surgery, Vanderbilt University School of Medicine, Nashville, will give the fifth annual Arthur Dean Bevan Lecture of the Chicago Surgical Society at the Chicago Woman's Club, October 20. His subject will be "Acute Circulatory Failure as Exemplified by Shock and Hemorrhage."

MAINE

Tumor Clinic—The Maine General Hospital has established a tumor clinic, to be held every Thursday. A 50-cent charge will be made to those able to pay. Physicians throughout the state or elsewhere are requested to refer their patients for diagnosis and advice or treatment. It is hoped to make the clinic self supporting.

MASSACHUSETTS

Anniversary Celebration at Harvard—The one hundred and fiftieth anniversary of Harvard Medical School was observed, October 6-7. The medical school was opened, Oct 7, 1783, with the induction into office of Dr John Warren as professor of anatomy and surgery, and Dr Benjamin Waterhouse as professor of the theory and practice of physic, and the exercises were arranged to celebrate that event. The anniversary ceremony began, October 6, with a program at the medical school on Longwood Avenue and three of its affiliated hospitals: Massachusetts General, Boston City Hospital and Peter Bent Brigham. At a formal program held in Cambridge, October 7, the original exercises of 1783 were repeated in part, including reading of the original inaugural orations of Professors Warren and Waterhouse, and the psalms sung 150 years ago. Dr Warren's oration was read by Dr J Lewis Bremer, Hersey professor of anatomy, and that of Dr Waterhouse by Dr Henry A Christian, Hersey professor of the theory and practice of physic. These chairs are the two oldest endowed professorships in the medical school. Following the establishment of the first two professorships in medicine at Harvard in 1783, instruction was given in Holden Chapel until 1810, when classes were transferred to Boston. The first medical school building was erected in 1816. From 1882 to 1906 the school occupied the building at the corner of Boylston and Exeter streets, now used by Boston University. The group of white marble buildings on Longwood Avenue was completed in 1906 and Vanderbilt Hall, the dormitory for medical school students, in 1927. In 1788 the university conferred its first medical degree on two students, and, in 1933 131 degrees. The present teaching staff numbers more than 130.

MICHIGAN

Dinner to Dr Chadwick—The personnel of the Detroit Department of Health gave a farewell dinner, September 15, to Dr Henry D Chadwick, who has resigned as controller of tuberculosis to become state health commissioner of Massachusetts. Dr William A Evans presided at the dinner and Henry F Vaughan, Dr P H was the principal speaker. John F Norton, PhD also received a tribute at the dinner. He resigned from the health department to become laboratory director of the Upjohn Chemical Company, Kalamazoo.

Society News—Dr Hugo A Freund addressed the West Side Medical Society, Detroit, October 5, on "Diseases of the Coronary Arteries."—Dr George C Leckie, Detroit, addressed the Lambton County Medical Society in Sarnia, September 13, on roentgen studies of the urinary tract.—Dr Charles E Boys, Kalamazoo, addressed the physicians of Manistee Lake and Oceana counties September 21 at a meeting sponsored by the Mason County Medical Society, he spoke on gonorrhea.—Dr Raymond W Waggoner, Ann Arbor spoke on epidemic encephalitis before the Washtenaw County Medical Society, October 10.

Dr Novy Appointed Dean at Michigan—Dr Fredenck G Novy was appointed dean of the University of Michigan Medical School, Ann Arbor, September 22. In the past Dr Novy has been chairman of the executive committee of the school, which includes also Drs Udo J Wile, James D Bruce, Harley A Haynes and Arthur C Curtis. He will continue in this capacity while also holding the deanship. Dr Novy received his medical degree at the University of Michigan Medical School in 1891. He became associated with his alma mater in 1886 as assistant in organic chemistry and has been professor of bacteriology and director of the Hygienic Laboratory since 1902. His completion of forty-seven years on the faculty of the university was observed in May when the Genesee County Medical Society gave him a testimonial dinner. The medical school has not had a dean since Dr Hugh Cabot's resignation in 1930.

MINNESOTA

Personal—Dr William J Mayo, Rochester, has recently been made a foreign associate member of the Paris Academy of Medicine.

Society News—Dr Axel C Baker, Fergus Falls, was elected president of the Northern Minnesota Medical Association at its recent annual meeting in Willmar. Other officers are Drs Julian F Dubois, Sauk Center, and Oscar O Larsen, Detroit Lakes, vice president and secretary, respectively. The next annual convention will be held at Thief River Falls.—The prize essay of the Minnesota Academy of Medicine by John Chaplin Barton was read at the meeting, October 11, the title is "The Distribution of Intranuclear Inclusion Bodies Primarily Involving Vascular Endothelium." Mr Barton will be a candidate for the degree of doctor of medicine at the University of Minnesota School of Medicine, Minneapolis, in 1934. Dr Bertram S Adams, Hibbing, presented a thesis on "Gallbladder Disease."

MISSOURI

Tuberculosis Conference—The tuberculosis division of the St Louis Health Department will conduct its second annual clinical conference, October 23-November 6 and November 13-27. Clinical demonstrations in the diagnosis of early tuberculosis will be presented at the tuberculosis division of Isolation Hospital and Koch Hospital. The course will be practical and free of charge. Registration will close, October 15. Physicians wishing to attend should communicate with Dr Hyman I Spector, 35 Municipal Courts Building, St Louis.

NEBRASKA

Society News—Drs Charles W Mayo and Jacob Arnold, Barge, Rochester, Minn., addressed the Elkhorn Valley Medical Society, Norfolk, August 25, on "Medical and Surgical Management of Malignant Lesions of the Descending Colon and Sigmoid", Drs Ralph H Luikart and Arthur D Dunn, Omaha, "Indications for Interference in Obstetrics" and "Position of Decapsulation of the Kidney in Urinary Suppression", respectively. Dr Dexter D King, York, was elected president.—Dr Benjamin J Clawson, Minneapolis, addressed the Omaha-Douglas County Medical Society, Omaha, September 26, on "Pathogenesis of Acute Rheumatic Fever."

NEW JERSEY

Society News—Henry F Vaughan, Dr P H, health commissioner of Detroit addressed a special meeting of the Medical Society of New Jersey at Newark, October 3, on the Detroit plan for medical participation in public health work.—The eastern section of the American Sanatorium Association held a meeting at Lakeland Sanatorium, October 6-7. Among speakers were Drs Louis H Clerf, Philadelphia, on "Bronchoscopy in the Treatment of Pulmonary Abscess and Bronchiectasis", Ronald V Christie, Montreal, Que. "Physiological Readjustments to Pneumothorax", and Frederick M Allen, New York, "Insulin in Tuberculosis Treatment".—Dr Ross V Patterson, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, October 13, on "Coronary Thrombosis with Special Reference to Its Differentiation from Abdominal Surgical Conditions."

NEW YORK

District Meetings—The annual meeting of the eighth district branch of the Medical Society of the State of New York was held at the Cataract House, Niagara Falls, October 5. At the morning session Dr Charles H Goodrich, Brooklyn spoke on medical economics, and Drs Ivan Hekimian and Henry E Vogel, Buffalo, presented a study of diabetic deaths.

At the afternoon session Drs Joseph C Bloodgood, Baltimore, and E Ellice McDonald, Philadelphia, spoke on cancer—At the annual meeting of the third district branch of the Medical Society of the State of New York, Haines Falls, September 5, speakers for the scientific session were Drs Edward M Livingston, New York, on 'Interpretation of Abdominal Signs and Symptoms' Gilbert Horrax, Boston, 'Certain Forms of Increased Intracranial Pressure and Their Treatment' and Samuel T. Orton, New York 'Some Varieties of Delayed Speech in Children'—At the annual meeting of the fourth district branch of the Medical Society of the State of New York in Malone, September 19, speakers included Drs Philip D Wilson and Frank H Lahey, Boston on 'Fractures and Dislocations of the Elbow' and 'Diagnosis and Management of Goiter' respectively, and John H Wyckoff, Jr., New York, 'Present-Day Evolution of Medicine'

New York City

Personal—Dr William J Fordrunk, Scarsdale, has been appointed head of the department of physiology and hygiene at Hunter College—Dr Thomas Darlington, health commissioner of New York from 1904 to 1910, celebrated his seventy-fifth birthday, September 24

Hospital News—Dr John E Daugherty has been appointed superintendent of Jamaica Hospital, Richmond Hill—An alumni association of interns of Fifth Avenue Hospital was formed, September 27, with Dr Eric R Skoluda as president—Midtown Hospital has recently organized a dermatologic service with Dr Jerome Kingsbury as director

Patients for Study at Rockefeller Institute—The Hospital of the Rockefeller Institute for Medical Research announces that the following diseases will be made the subject of special investigation during the coming winter: acute respiratory diseases, chickenpox, measles, rheumatic fever, heart disease, nephritis, anemia (aplastic, idiopathic, pernicious or severe microcytic), sprue, severe glossitis or stomatitis without anemia and a limited number of cases of epidemic encephalitis. Suitable patients may be referred to the hospital by physicians and others willing to cooperate. No charge is made for any services. Physicians should communicate by telephone or in person with the resident physician before sending patients.

Memorials to Pioneer Diphtheria Investigators—The twentieth anniversary of the introduction of diphtheria antitoxin into the United States and of the Schick test will be celebrated as part of the children's health fetes to be held as the climax of the immunization campaign now in progress in Bronx and Queens counties. Memorials signed by thousands of immunized children in the two boroughs will be presented to Dr William H Park, director of the bureau of laboratories of the New York City Department of Health, the pioneer in the use of antitoxin in this country and to Dr Bela Schick, who developed the test by which immunity may be demonstrated. It is hoped to reach about 80,000 unimmunized children during the present campaign.

OHIO

Conference of Health Officers—The fourteenth annual conference of health officers of Ohio will be held in Columbus, October 19-20. Among speakers will be Drs John H J Upham, Columbus, chairman, Board of Trustees, American Medical Association, on 'Postgraduate Work in Public Health', Edward S Godfrey, Jr., of the New York State Department of Health, Albany, 'Modern State Health Regulations' and Mr William R Foss, state representative from Mercer County, 'What Is Wrong with Our Present Health Laws'.

Illegal Practitioner Fined—Frank E McCartney, Cleveland is reported to have been fined \$200 and costs and sentenced to serve sixty days in the workhouse on a charge of manufacturing water for use as a medicine and \$300 and costs on a charge of practicing medicine after trial in police court, September 1. It appears that the man, who was listed in the city directory as a physician—which he is not—had given electrical treatments to a woman and sold her five gallons of McCartney's Electrified Water for \$10. Analysis of the water is reported to have shown that it was ordinary Lake Erie water. McCartney was released on \$1,000 bond pending motion for a new trial.

Memorial Meeting—An all day conference on tuberculosis will be held at State Senatorium, Mount Vernon, October 18 as a memorial to Dr Charles O Probst. Dr Herbert M Platter, Columbus, Mr James E. Bauman, assistant state director of health and Mr W H Ditto, sanitary engineer of the Mahoning Valley district will summarize Dr Probst's

work in public health. Medical aspects of tuberculosis will be discussed by Drs Charles A Doan and Bruce K Wiseman, Columbus, and surgical aspects by Dr George M Curtis, Columbus. Dr Probst, who died April 2, was for twenty-five years secretary of the state board of health and served as president of the American Public Health Association, Ohio Society for the Prevention of Tuberculosis and the Conference of State and Provincial Boards of Health.

Society News—A symposium on epidemic (lethargic) encephalitis was presented at the first fall meeting of the Columbus Academy of Medicine, September 18, by Drs John H Hayes, Edson J Emerick and Roswell S Fidler—Dr George I Nelson, Columbus, addressed the Greene County Medical Society, Xenia, September 15, on cardiovascular diseases—Drs Edward J McCormack and Thomas L Ramsey, Toledo, addressed the Seneca County Medical Society, Tiffin, September 21, on medical ethics and medical history, respectively—Dr Fred M Douglass, Toledo, addressed a meeting of the Marion County Academy of Medicine, September 5, on 'Management and Treatment of Biliary Infection'—Dr George M Curtis, Columbus was guest speaker at the first fall meeting of the Mahoning County Medical Society, Youngstown, September 19, on 'Significance of the Iodine Content of Human Blood'—Dr Walter G Stern, Cleveland, addressed the Summit County Medical Society, Akron, October 3, on 'The Doctor in Court'.

OKLAHOMA

Society News—Dr Edward A Abernathy, Altus, among others addressed the Western Oklahoma Medical Society, September 19 on 'Acute and Suppurative Otitis Media and Its Complication'—The Grayson County (Texas) Medical Society held a joint meeting with the Marshall County Medical Society at Durant, September 12. Speakers included Drs David C Enloe and Arthur Gleckler, Sherman, Texas, on 'Treatment of Empyema' and 'Treatment of Mental Cases in the Home,' respectively—Drs Carroll M Pounders and William M Taylor, Oklahoma City, addressed the quarterly meeting of the Canadian County Medical Society, El Reno, September 18 on 'The Child Who Is Susceptible to Colds' and 'Nutritional Disturbances in Early Life,' respectively. Physicians of Blaine, Custer and Kingfisher counties were guests at the meeting.

PENNSYLVANIA

Society News—Dr Howard K Petry, Torrence, spoke on mental health before the Fayette County Medical Society, October 5, in Uniontown. Drs Roy R Snowden and Waid E Carson, Pittsburgh, addressed the society, September 7, on 'Recent Advances in Knowledge of Nephritis' and 'Changes in the Eye in Diseases of the Kidneys,' respectively, and Dr Jean V Cooke, St Louis, discussed the encephalitis epidemic—Dr Oliver H Perry, Pepper, Philadelphia, addressed the Berks County Medical Society, Reading, September 12 on blood dyscrasias—Dr Damon B Pfeiffer, Philadelphia, addressed the Lehigh County Medical Society, Allentown, September 12 on 'Cancer of the Intestines, Rectum and Colon'.

Philadelphia

Society News—The first autumn program of the Philadelphia County Medical Society, October 11, was devoted to mental hygiene. Dr Charles W Burr gave an address on 'What Is a Good Environment?' and Dr Edward A Strecker, Mental Hygiene and the General Practitioner—Speakers at the first meeting of the Philadelphia Academy of Surgery, October 2 were Drs Charles H Frazier and William H M Ehrh on 'The Superior Laryngeal Nerve and the Superior Pole in the Thyroidectomies' and Maxwell Cherner, 'Etiology of Indirect Inguinal Hernia'—A symposium on prenatal care was presented before the Obstetrical Society of Philadelphia, October 5 by Drs Robert M Shure, Edward A Schumann, Joseph V Missett, Jr., Frances S Dunne and Samuel M Stern.

TENNESSEE

Personal—Dr Ross L Gauld, Johnson City, has been appointed health officer of Maury County to succeed Dr Haiman C Busby, Columbia, who has gone to Johns Hopkins University for a year's study of public health under an award from the Rockefeller Foundation—Dr Waller S Leathers, Nashville, was elected chairman of the new state public health council at its first meeting in Nashville, September 15—Employees of the Davidson County Isolation Hospital entertained Dr William W Core, superintendent of the institution for thirty-three years at a dinner, September 16, in honor of his seventy-fourth birthday.

Society News—Dr Daniel R. Thomas, Calderwood, addressed the Blount County Medical Society, Maryville, October 5, on causes and treatment of asthma. Dr Kuebel A. Bryant spoke on first aid in ophthalmic injuries.—Dr Jack Witherspoon addressed the Nashville Academy of Medicine at its opening session of the fall, September 5, on "Hemorrhage and Diverticulitis of the Colon." Dr Lucius E. Burch spoke, October 2, on cancer of the cervix and uterus.—Dr Giles A. Coors, Memphis, among others, addressed the medical society of Dyer, Lake and Crockett counties September 6, on surgical mortality.—Dr William D. Haggard, Nashville, spoke on goiter at a meeting of the Gibson County Medical Society, Trenton, August 28.—Dr Edwin H. Magee, Chattanooga, was the speaker at a meeting of the Hamilton County Medical Society, Chattanooga, October 5, on "Complications of Cervical and Perineal Lacerations."—Dr Robert C. Anderson, Johnson City, among others, addressed the Washington County Medical Society, October 5, on granuloma inguinale.

VIRGINIA

Health at Richmond—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended September 30 indicated that the highest mortality rate (168) appeared for Richmond and the rate for the group of cities, 10. The mortality rate for Richmond for the corresponding week of 1932 was 116 and for the group of cities, 9.4. The annual rate for eighty-five cities for the thirty-nine weeks of 1933 was 10.9 as against a rate of 11.2 for the corresponding period of last year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

WEST VIRGINIA

Personal—Dr Chesney M. Ramage, Fairmont, has been appointed superintendent of Fairmont Emergency Hospital succeeding Dr William A. Welton.—Dr Reece M. Pedicord has been appointed health officer of Wheeling and Ohio County, succeeding Dr William H. McLain.

Society News—The Fayette County Medical Society entertained medical societies of adjacent counties at the Oak Hill Country Club, September 12 with a golf tournament in the afternoon followed by dinner and a scientific meeting. Dr Thomas W. Murrell, Richmond, Va., presented a paper on dermatology and syphilology.—The Hospital Association of West Virginia held its eighth annual meeting in Clarksburg, October 3.—Dr Maxwell E. Lapham, Philadelphia, who has been conducting extension courses in obstetrics in Virginia for several months, addressed the Mercer County Medical Society, Bluefield, September 8 on operative obstetrics.—Dr Sylvester J. Goodman, Columbus, Ohio, addressed the Monongalia County Medical Society, Morgantown, August 1, on "Treatment of Postpartum Hemorrhage and Progress of Obstetrics."—Dr Robert T. Miller, Jr., Baltimore, addressed the Ohio County Medical Society, Wheeling, October 6, on surgical treatment of pulmonary tuberculosis.

GENERAL

Neurologic Congress—At a preliminary conference in London, September 7, to arrange for the second International Neurological Congress, to be held there in August, 1935. Sir Charles S. Sherrington, Oxford, England, was elected president. Dr Bernard Sachs, New York, honorary president, and Dr Gordon M. Holmes, London, England, acting president.

Society News—Dr W. Wayne Babcock, Philadelphia, was installed as president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons at its recent annual meeting, and Dr Marvin P. Rucker, Richmond, Va., was chosen president-elect. Dr Magnus A. Tate, Cincinnati, was reelected secretary. The next annual session will be held, Sept. 8-10, 1934.

International Conference on Tuberculosis—The next conference of the International Union Against Tuberculosis will be held in Warsaw, Poland, Sept. 4-6, 1934. Subjects selected for discussion are: (1) biologic variations of the tubercle bacillus, (2) the various forms of osteo-articular tuberculosis and their treatment and (3) utilization of dispensaries for the treatment of tuberculous patients. The National Tuberculosis Association, 450 Seventh Avenue, New York, is arranging a special party for the Warsaw meeting. Those who wish to

travel with the group may obtain further information from the association.

Health in the Byrd Expedition—Members of Admiral Richard E. Byrd's second expedition to the antarctic region, which was to set out from Boston, September 25, all received thorough physical examinations under the direction of Dr Joel E. Goldthwait, Boston, and Dr Guy O. Shurey, recently of Tucson, Ariz., surgeon of the expedition. Members of the first expedition in 1928 were examined in New York and complete physical records were placed on file with the surgeon of the expedition, including blood grouping in case transfusion were necessary in an emergency. The expedition returned without the loss of a man. Fourteen men who went on the first trip have been selected for the second.

Awards of Merit—The American Congress of Physical Therapy has presented awards of merit for 1933 to the following:

Dr Claudius Regaud, associate director, Curie Institute, Paris, for meritorious work with radium.

Dr Walter J. Turrell, University of Oxford, for merit in physical medicine.

Dr Harvey Cushing, Sterling professor of neurology, Yale University School of Medicine, New Haven, for merit in developing electrosurgery.

Dr Gustavus M. Blech, Chicago, for pioneer literary work in physical medicine.

Dr Gustav Bucky, New York, for merit in radiology.

Dr William L. Clark, Philadelphia, was named president-elect of the congress and Dr Albert F. Tyler, Omaha, was installed as president. Other officers elected were Drs John S. Hibben, Pasadena, Calif.; William Bierman, New York; Frederick L. Walrer, Marshalltown, Iowa; and Walter P. Grimes, Kansas City, Mo., all vice presidents, Nathan H. Palmer, New Orleans, secretary, and John S. Coulter, Chicago, treasurer, reelected. The 1934 session will be in Philadelphia.

Death Rate Lowest on Record—The general death rate for continental United States for 1932 was 10.9 per thousand of estimated population, the lowest rate ever recorded since the collection of mortality statistics was begun in 1900. The rate is based on reports from the U. S. Death Registration Area (exclusive of Utah) which is estimated to represent 96.3 per cent of the population of the United States. The Bureau of the Census has issued comparative figures for the years 1930-1932 showing the death rates from individual causes. In eighteen groups of causes into which the table is divided, thirteen groups showed decreases in the total number of deaths, three showed increases and two remained about the same. Groups in which large increases occurred were cancer and other malignant tumors and diseases of the circulatory system. In 1932 there were 255,802 deaths from cancer of the stomach and duodenum, 14,871 from cancer of the uterus, 11,863 from cancer of the breast and 10,420 from cancer of the liver and biliary passages. Deaths from diseases of the circulatory system increased numerically from 280,403 in 1930 to 294,596 in 1932. A noteworthy decrease was in tuberculosis, which caused 9,000 fewer deaths in 1932 than in 1930, a decrease in rate from 71.7 to 6.3.

Society Elections—Drs Eben J. Carey, dean, Marquette University School of Medicine, Milwaukee, and Chevalier Jackson, professor of bronchoscopy and esophagoscopy, Temple University School of Medicine, Philadelphia, were awarded the annual gold medals for research of the Radiological Society of North America, September 29. The award to Dr Carey was in recognition of his x-ray study of bone growth and to Dr Jackson for his work in removing foreign bodies from the trachea and lungs with the aid of the x-rays. Dr Carey is director of medical exhibits at A Century of Progress. New officers of the organizations making up the first American Congress of Radiology in Chicago, September 25-30, are as follows:

RADIOLOGICAL SOCIETY OF NORTH AMERICA

President: Dr W. Herbert McGuffin, Calgary, Canada.

President Elect: Dr Lloyd Bryan, San Francisco.

Secretary: Dr Donald S. Childs, Syracuse, reelected.

AMERICAN ROENTGEN RAY SOCIETY

President: Dr John T. Murphy, Toledo.

President Elect: Dr George W. Grier, Pittsburgh.

Secretary: Dr Eugene P. Pendergrass, Philadelphia, reelected.

AMERICAN RADIUM SOCIETY

President: Dr Rollin H. Stevens, Detroit.

President Elect: Dr William H. Cameron, New York.

Secretary: Dr Edward H. Skinner, Kansas City, Mo., reelected.

AMERICAN COLLEGE OF RADIOLOGY

President: Dr Henry K. Pancoast, Philadelphia.

President Elect: Dr Thomas A. Groover, Washington, D. C.

Secretary: Dr Benjamin H. Orndoff, Chicago, reelected.

LONDON

(From Our Regular Correspondent)

Sept 23, 1933

The Number of Physicians in Great Britain

In a review of the numerical strength of the medical profession, the *British Medical Journal* gives figures showing a steady increase of the proportion of physicians to the population in the last fifty years. The following are the numbers at decennial intervals

Year	Physicians on Register	Population of British Isles
1831	23 275	35 241 482
1891	29 555	38 104 975
1901	36 912	41 976 827
1911	40 913	45 340 330
1921	45 408	47 146 366
1931	55 604	48 959 455

These figures show that while the number of physicians in 1921 was nearly double that in 1881, the population had increased only 34 per cent. During the last ten years the number of physicians has increased by 10 000 while the population has increased by much less than 2,000 000. Making allowance for the large number of registered physicians living abroad and for those no longer in practice, the proportion of physicians to population is more than one to every thousand. In the United States it is estimated that there is one to every 800, in Austria, one to 900 in Switzerland one to 1,250, in Germany, one to 1 345 in Denmark one to 1,430, in France, one to 1,510 in Holland, one to 1,820 in Czechoslovakia, one to 1,970, and in Sweden one to 12,860

The German Persecution of Physicians

The number of Jewish physicians who have sought refuge in this country from the German persecution has been exaggerated by certain journals desiring to raise a scare about British jobs being endangered at this time of depression. It is officially stated by a subcommittee of the Jewish Medical and Dental Emergency Association that the number of German physicians and dentists who have so far registered with the committee does not exceed 180 and that only about eighty to a hundred of them are endeavoring to obtain a British qualification. Of these, thirty-five have been placed at Edinburgh and three or four have been admitted to most of the medical schools in Great Britain and northern Ireland. As pointed out in a previous letter the persecution is not confined to the Jews but is directed against all persons who show pacifist or liberal opinions. But the physicians who have sought refuge in this country appear to be all Jews. The opposition which has arisen on a limited scale in certain quarters disclaims any intention to obstruct the admission of Jewish research workers and leading specialists or of physicians in limited numbers. In the case of scientists, no opposition of any kind has been manifested. Six German Jewish professors have been appointed to two years research fellowships in history, economics, physics, psychology and physiology at Manchester University. Four German specialists including a physician a gynecologist and a bacteriologist have accepted posts at the Victoria Jewish Hospital Manchester. Last June Michael Polanyi the Hungarian physical chemist who resigned his Berlin professorship as a protest against Nazi treatment of Jewish professors was appointed to the chair of physical chemistry in the University of Manchester. The formation of the Academic Assistance Council under the presidency of Lord Rutherford to assist

refugee scientists has been described in a previous letter. The council has raised \$50,000 by voluntary subscription and is aiming at raising \$200,000. It has allotted \$1,000 a year each to fifty refugee scientists.

Poisonous Metallic Dusts

An investigation by two chemists, Dr T J Dunn and Mr H C L Bloxham, of the unexplained deaths of cattle who grazed in different parts of the county Durham has shown how the atmosphere can be polluted by the emanations from coke ovens, which were found to be in proximity in all cases. The pasturage in the neighborhood was found to contain lead. In the stomach and intestine of one of four bullocks that had died unexpectedly lead copper and manganese were found. The owner of a farm near the coke ovens had lost thirty animals, while others which were moved to other pastures on becoming ill, recovered. Nothing was found in the water to explain the death of the animals but in the grass lead and copper were found to the extent of 14 and 47 parts per million respectively. The internal organs of the animals contained lead in the following proportions per million stomach tissue, 0.6, kidneys, 17 liver, 2.6. These organs also contained respectively, 3.2, 2.1 and 3.5 parts per million of copper. The source of these metals seems to be the pyrites in coal, which may contain lead in proportions varying from 20 to 54 parts per million.

Dunn and Bloxham have also drawn attention to the prevalence of metallic dusts in the air of manufacturing towns, as a result of the combustion of coal both in houses and in furnaces. Analyses of various kinds of coal and of domestic and industrial soots revealed lead varying from 5 to 461 parts per million. The various kinds of dusts deposited in different open areas of Newcastle and on shelves of houses porticoes and the entrances to public buildings revealed lead to the extent of 3,000 parts per million, copper 1,600, zinc 4 700 and arsenic 400. Also, while the pasturage of purely rural districts was found to be free from lead, it was found in vegetation growing along roads where there was much automobile traffic. This was attributed to the tetra-ethyl lead present in some gasoline.

The Decline of Vaccination

The decline of vaccination, following the practical abolition of compulsion (by allowing a conscientious objection of the parent to vaccination to secure exemption) is causing concern to the public health authorities. The official figures show that only 39 per cent of the children born in 1931 (the last year for which statistics are available) were vaccinated compared to 75 per cent in 1905. The following shows the downward trend in the last five years.

Year	Percentage Vaccinated	Percentage of Conscientious Objections
1927	43.2	41.2
1928	42.6	42.5
1929	39.9	44.7
1930	40.1	45.6
1931	39.0	46.7

The Spread of Typhoid by Unrecognized Cases

In recent years typhoid has greatly diminished in this country as a consequence of improved hygiene. The sporadic cases and the occasional outbreaks that still occur are attributed mainly to typhoid carriers. In the *Glasgow Medical Journal*, Dr C M Smith has described important work done by the public health department of Glasgow in connection with typhoid. In the last eight years 800 cases of verified typhoid occurred in Glasgow and 1 608 contacts were examined bacteriologically in order to ascertain whether they were carriers. Of these, fifty-eight proved to be carriers and fell into three groups

fourteen chronic carriers, ten temporary carriers and thirty-four recent "missed" cases (contacts who had recently an illness which might have been a very mild attack of typhoid) The conclusion is drawn that these cases, which considerably outnumber the carriers, now play a larger part than the latter in the spread of typhoid in Glasgow The chronic carriers, the number of whom may be underestimated, were found to be responsible for only twenty cases During the eight years, only one case could be attributed to the cases of typhoid treated in hospitals The 800 cases were made up of 529 sporadic cases and 271 that occurred in outbreaks, of which the largest was one of sixty-two cases of paratyphoid B in 1927 The origin of the sporadic cases frequently could not be traced In Glasgow carriers are prohibited from engaging in any occupation with food It is held that the only efficient treatment of the carrier is excision of the gallbladder, but this operation is almost always declined

The Sanatorium and the Campaign Against Tuberculosis

For several sessions the Academy has been the scene of a discussion between several of its eminent members on the place of sanatoriums in the organization of the crusade against tuberculosis The discussion was precipitated by Professor Sergent, who complained that the sanatorium in the treatment of tuberculosis is being belittled A number of these institutions have been created, and others are being proposed This represents an enormous expenditure of money In the meantime public opinion is developing to the effect that the progress made in the treatment of tuberculosis with pneumothorax phrenicectomy, apicolysis and aurotherapy render the stay in a sanatorium useless so that patients might just as well be treated at home under the supervision of experienced physicians What Mr Sergent did not say is that sanatorium treatment, unless the patient is indigent and is treated gratuitously, is exceedingly expensive A Paris physician, who has a son in a sanatorium, expends, owing to pneumothorax treatment with repeated insufflations and continual radiographic examinations, an annual sum exceeding 40 000 francs, and this in spite of the fact that he has the benefit of reduced rates At present the sanatorium is available only to the indigent, whose expenses are paid by the government, and to millionaires This is the reason why middle class patients avoid the sanatorium, to which may be added an unwillingness to live, for years, a life of idleness away from their families Family physicians are inclined to encourage these sentiments Mr Sergent was the first to protest against the abandonment of sanatorium treatment, which in his opinion, has no substitute, as it combines the essential conditions on which is based the logical treatment of tuberculosis isolation, pure air, absolute rest, constant medical supervision and training of the patient in a mode of living that he must henceforth follow The new forms of treatment give much better results when they are applied by competent persons in the atmosphere of the sanatorium Mr Rist agreed that sanatorium treatment should remain the basis of the general treatment of tuberculosis The necessary physical and mental rest is impossible to secure at home, and among the masses the tuberculous person does not always find in his family the encouragement needed as the family frequently does not understand the gravity of the situation The educative role of the sanatorium must not be forgotten The patient learns here how to take care of himself By making admission to sanatoriums easier one combats the baneful influence of treatment by charlatans Mr Hayem thought that some directors of

sanatoriums do not take sufficient account of digestive disorders, so frequent in tuberculous persons Forced feeding is not suitable for all patients Overweight, contrary to current opinion, is not a sure sign of improvement in tuberculous persons Mr Leon Bernard emphasized that it is important to oppose public opinion that undermines the sanatorium for reasons of personal convenience Mr Bezançon, in agreement with Mr Sergent, ascribed first place to the sanatorium in the crusade against tuberculosis He opposed, however, the idea that all a tuberculous person needs is to consent to a protracted stay in a sanatorium and that recovery outside of a sanatorium is impossible He suggested a modification of that idea The sanatorium should admit not merely patients in the beginning stage, who present simple congestion and are not contagious but also acute febrile types It is the type of expensive sanatorium, whose benefits are too transitory, to which Mr Bezançon had declared he preferred active treatment in the specialized urban hospital Hence the misunderstanding that arose The new idea is to create therapeutic centers of two types an urban type for diagnosis, the selection of patients, and the preparation for and the institution of ambulant pneumothorax, and an extra-urban type corresponding in a general way to the sanatoriums of former days Mr Bezançon pointed out that, to prevent the urban therapeutic centers from becoming overcrowded, it is desirable that a greater number of patients be deflected toward the sanatorium If more urban centers for treatment of the tuberculous are to be created, there should be an increase in the number of sanatoriums, in order that the present spectacle of patients being compelled to wait months before securing admission may cease Bezançon emphasized that the crusade against tuberculosis is, to a great extent, identical with the promotion of general hygiene

Lectures in Military Hospitals

Through the initiative of the general management of the army medical corps, a series of lectures by university professors is being organized in the military hospitals As the Milan Military Hospital Prof Carlo Foa, director of the Physiologic Institute at the University of Milan delivered a lecture on the "Metabolism of Calcium in Disorders of the Skeleton" The speaker said that calcium is present in every cell of the animal organism and is needed for the life and the functioning of every tissue The normal source of calcium is the food, but absorption by this route does not take place readily and a large part of the calcium in the food is eliminated with the feces The calcium-phosphorus quotient in the diet is important The optimal value is 1.3 as in human milk The bile in which calcium is soluble, plays an important part in the exchange of calcium The subcutaneous or intramuscular injection of the parathyroid hormone increases the concentration of calcium in the blood serum Such increase is gradual and attains the maximum (occasionally 18 mg per hundred cubic centimeters) in from twelve to eighteen hours The skeleton can take on or yield up calcium according to the needs of the body, for the mineral constituents of the bones undergo a continuous change Professor Foa described the various forms of parathyroid osteosis ankylosing polyarthritis due to hyperfunctioning of the parathyroids, Paget's disease and Recklinghausen's disease In some cases of osteomalacia there might be a diagnosis of hyperparathyroidism, and operations on the parathyroids would in that case be justified.

In the military hospital at Messina, Professor Izar, director of the Clinica Medica at the University of Messina, lectured on Amebiasis The port of entry of the parasite is always

oral, indirect contagion is possibly the most common. The liver is the most frequent seat of metastasis. The amoeba reaches the liver by the portal route and may produce various clinical forms of hepatitis and also abscess. The treatment of amebiasis rests largely on emetine, combined with arsenical preparations and purgatives, and possibly hepatocentesis.

Research on Lysocytin and on Nerve Regeneration

The Academy of Medicine of Turin met recently under the chairmanship of Professor Vanzetti. Belfanti presented a paper on the disintegration of lecithins. The enzymes present in snake venom may transform lecithin into a highly toxic substance, which hemolyzes red corpuscles and is termed "lysocytin." Lysocytin has been isolated from some organs of certain mammals, particularly from the pancreas of the horse; this transitory terminal substance is then transformed into nontoxic phosphatides. Belfanti has succeeded in isolating lecithinase from the pancreas of the horse; it is on lecithinase that the function of transforming lecithin into lysocytin depends. Japanese investigators assert that they have found lysocytin in polished rice and that it is identical with the defective diet toxin that is thought to be the cause of beriberi. The speaker demonstrated, in agreement with Contardi, that the belief in the action of lecithin as the cause of beriberi is erroneous.

Goria suggested a device for maintaining the course of tertian malaria in inoculation malaria. The device consists in taking the blood during the period of apyrexia, defibrinating it, adding mercury cyanide, and injecting the plasma intravenously. With this procedure malarial inoculation becomes practicable even in patients with weak resistance, and one avoids the dangers due to the development of daily febrile attacks or too violent attacks of fever.

Dagliotti reported experiments in which he divided the sciatic nerve of dogs at the hip and then separated the fibers of the central stump and sutured only a small part of them to the peripheral stump. A few months later by means of laminectomy, he destroyed the sensory fibers and removed the six larger spinal ganglions on the side previously operated on. After from eighteen to twenty-one months the dogs were killed and it was found that in them function was perfect. The muscles of the two limbs had acquired an almost identical weight. The nerve fibers were counted at various heights, and it was observed that from a central stump containing 2,000 myelonic, almost exclusively motor fibers about 4,000 fibers had been regenerated which were distributed in a homogeneous manner among all the fasciculi of the peripheral stump. The histologic preparations of the muscles revealed a greater volume of the fibers of the muscles on the side operated on but there were fewer of them. According to the author these results may justify attempts to bring about a numerical increase of the nerve fibers that survive in forms of partial paralysis of a nerve, by means of simple transversal neurotomy of that nerve and precise apposition and suture of the stumps. This intervention, suggested by Purpura in October 1931 had been performed by the speaker a few months previously, in a child with severe paralysis of the lower limbs due to an attack of poliomyelitis eight years previously. Three years has now elapsed since the intervention and some improvement may be noted.

The Sanitary Condition of the Army

The Direzione generale di sanità militare has published a report on the sanitary condition of the army in 1929 which reveals that the morbidity which in 1928 was 573 per thousand declined in 1929 to 546. The mortality was 31 per thousand of the average number enlisted which marked a decline over previous years. The average number of hospital patients per thousand effectives was 20.9. Considered by organization the

greatest morbidity was found among the newly enlisted infantry and the least morbidity among the seasoned infantry. The morbidity was highest in the month of July and the lowest during the last three months of the year. The most frequent disorders with which the troops were affected were conditions of general malaise (244.9 per thousand patients), infectious fevers of short duration, and muscular rheumatism. Of the average force present, 1.9 per thousand came down with typhoid or paratyphoid infection, resulting in a case mortality of 16 per cent. The cases of undulant fever amounted to 0.1 per cent of the average force, with no deaths; there were no cases of smallpox; there were 4.2 per thousand cases of measles, with a mortality of 0.3 per cent. The cases of scarlet fever amounted to 0.2 per thousand, with a mortality of 3.6 per cent. Influenza presented a morbidity of 12.3 per thousand, with a mortality of 0.07 per thousand. One infantryman was attacked by leprosy. The cases of venereal disease treated in the military sanitary institutions amounted to 25.8 per thousand of the average force while the cases of malaria detected were 7 per thousand, and the cases of acute articular rheumatism were 4.1 per thousand. Tuberculosis developed in 2.7 per thousand troops. Of the cases of tuberculosis diagnosed, 52.4 per cent concerned the respiratory apparatus, and 47.6 per cent other organs. Of the men admitted to institutional care for tuberculosis, 23.7 per cent died. In all the military hospitals taken together, 8,058 operative interventions were performed.

Aiding Orphans of Physicians

Under the chairmanship of Generale Medico Della Valle, a meeting was held recently of the committee for the aid of orphans of physicians who died during their war service. The chairman stated that the work will continue and will not be completed until 1942. Up to the present time, sixty-five orphans have been aided, forty-eight of whom have been granted funds with which to pursue their studies.

Syndicate of Physicians

Although there are not too many physicians in Yugoslavia, their situation has become difficult since the World War. This is due not only to the bad economic conditions in the country but also to a vigorous effort to socialize medicine since 1925. A number of public health institutions have been opened, unfortunately these institutions do not only preventive and diagnostic work but also curative work free especially for the treatment of venereal and infectious diseases. Imitating the state many private institutions and associations have taken physicians into their service for a minimal monthly pay such as social insurance, railway companies miners and maritime companies. The state physicians are the only ones who have an assured income and a pension after thirty five years of active service. Besides they are allowed to have private appointments in any of the institutions mentioned where they work after their regular service hours. As all the positions in the state services are taken, newly qualified young physicians are obliged to begin as private practitioners so that the number of private physicians is constantly increasing and their earnings are diminishing. In such a situation they finally decided to create a syndicate although the official chamber of physicians has already been in existence for ten years. The chamber of physicians is only an administrative representation of all physicians of the country. In reality the interests of private physicians and of state physicians are rather opposed and that is why the former decided to unite in a syndicate.

The aim of the syndicate is to protect the interests of its members by determining minimal fees by just distribution of

appointments, by aiding its members in the case of sickness or unemployment, by controlling medical competition, and by diminishing unemployment among physicians. The syndicate will survey medical ethics and will judge and pass resolutions in the case of breach of medical ethics of its members. The syndicate will combat chiropody and try to prevent such practice. Every salaried service will be regulated through the syndicate. Every member has to pay an annual subscription for membership and a monthly subscription for the sickness fund. During unemployment or during sickness, the members do not pay their subscription if the unemployment lasts more than six months. Each member will receive a subsidy during unemployment or sickness if it lasts more than ten days. If a member is called before the court for professional delinquency he will also receive this subsidy. In case of death of a member, his family receives compensation; this compensation is given for members over 40 years of age if they have been members for a period of fifteen years, for younger members ten years of membership gives the right to claim the same compensation.

The Number of Physicians in Yugoslavia

There are 4,951 physicians for a population of 14,170,000, that is, one physician for 2,862 inhabitants. There is an uneven distribution of physicians in Yugoslavia. The cities have 4,059 physicians, whereas the villages have only 812. Belgrade has 768 physicians, or one for 325 inhabitants. A similar ratio exists for nearly all cities. Living conditions in the villages are not so good and the earnings are insignificant. There are 1,299 physicians as state officials, including 402 for curative medicine in districts, 477 in hospitals and 420 for preventive medicine. In social insurance institutions there are 1,409 physicians. This means that there are 2,708 physicians with permanent pay and an assured pension and 2,243 working as private practitioners. While there are not too many physicians in the country their situation is becoming worse every day because the population cannot afford to pay private physicians and are going to university clinics and other state institutions where examination and treatment are given free of charge. Actually, according to general health conditions of the population, a larger number of physicians is required.

Infectious Diseases During 1932

There was nearly the same number of infectious diseases during 1932 as during 1931. The eleven diseases most widespread in the country are typhoid and paratyphoid fever, typhus fever, dysentery, scarlet fever, measles, diphtheria, cerebrospinal meningitis, tetanus, anthrax and acute poliomyelitis. Of these eleven diseases, in 1932 there were 248 cases for each 100,000 inhabitants and in 1931 a little more, 255.

The mortality from these eleven diseases was 9.29 per cent in 1932 and 9.32 per cent in 1931. In 1932 diphtheria and croup took first place with 10,158 cases and 1,208 deaths and measles had the second place with 6,956 cases and 106 deaths. There were 6,908 cases of typhoid, with 746 deaths. 4,383 cases of scarlet fever, with 296 deaths and 2,656 cases of bacillary dysentery, with 302 deaths. There were only 122 cases of cerebrospinal meningitis, with 56 deaths, or a mortality of nearly 46 per cent.

Professor Blumenthal Comes to Belgrade

Invited by the faculty of medicine in Belgrade, Prof. Dr. Blumenthal of Berlin has come to Belgrade having accepted the appointment as professor. He came with his assistant Dr. Jacob. Professor Blumenthal has taught in Berlin since 1905. He has devoted his life to the study of cancer. In 1917 he was appointed director of the institute for cancer research in Berlin and general secretary of the German Society for Cancer. He has written two well known books, "Chemical

Processes in Cancer" and "The Results of the Experiments with Cancer." Professor Blumenthal will continue in Belgrade his experimental work on cancer in the Institute of Pathology, brilliantly equipped by the late Prof. Georges Joannovic. As soon as he comes back from the international congress on cancer in Madrid he will begin teaching.

The Fate of the Hajek Clinic

There are probably few American physicians who studied in Vienna without having visited Professor Hajek's rhinolaryngologic clinic, which had an excellent international reputation. In July of this year, after completion of his honorary year, Hajek bade farewell to his clinic. The laws of Austria require every clinical teacher to give up teaching on reaching his seventieth birthday. By exception, he may be granted an 'honorary year,' on completion of which he must, however, resign. Professor Hajek, as stated, had completed his honorary year, and the farewell celebration held in July was an ovation in evidence of the esteem in which the scientist was held by all who knew him. Representatives of all the scientific bodies participated in the farewell ceremonies. Unfortunately, it has recently been announced by the authorities that the Hajek clinic is to be discontinued and that only the otologic clinic will be retained and will take over the work of the Hajek clinic in rhinolaryngology, in which instruction by first-class specialists will continue to be given. The old controversy as to whether otology should constitute a specialty distinct from rhinolaryngology or whether they should be united, has been decided here in favor of their union. It remains to be seen whether the former conception offered better possibilities from the scientific and theoretical points of view. The friendly rivalry of the two clinics existing in Vienna proved advantageous to the medical profession for the two clinics were thus forced to do their best. Financial considerations were of such moment to the government that it was induced to discontinue a clinic that had a well organized staff and equipment and attracted many foreign students. The clinic, which was founded more than fifty years ago by the old masters of laryngology (Türk and Schrotter), and whose traditions exerted a remarkable influence, will probably turn over its quarters to a surgical clinic, although no final announcement as to their disposition has as yet been made.

Austrian Law on Sterilization of Males

In connection with a complaint brought against three physicians and their aids, who, during last year, had sterilized a large number of men by means of vasoligation and vasectomy, the supreme court decided the question as to whether such an intervention can be judged according to Austrian law, as a grave bodily injury and punished accordingly. The accused were all acquitted, on the ground that the law still in force did not justify the imposition of a sentence. The present law covers only an 'incurable' permanent injury caused by operation. At the trial, experts testified that by means of another operation the sterilization might be eliminated. Thus the physicians could not be punished for a 'permanent and incurable' injury to health. The law demands also evidence of "an unfriendly purpose" or "a design to maltreat" the person injured, on the part of the accused, and that evidence is not available if the patients have accepted the operation of their own free will. Moreover, no injurious effects of the operation have been demonstrated in a single case. It was found to be impossible to convict the accused on the basis of the paragraph of the Austrian law prohibiting charlatanism. "Charlatanism" is defined in Austria as 'unauthorized' treatment, that is to say,

by persons who, neither by virtue of their studies nor by reason of permission granted by the authorities, have the right to render medical aid to patients. The court held that the penal code now in force precludes legal prosecution for the performance of sterilization. The law shows here a defect and new legislation is an urgent need.

The New Austrian Ethical Code

The government recently submitted, for criticism, to representatives of the medical profession of the republic, the draft of a new ethical code and council of physicians and requested a prompt return of the opinion of the profession in regard to the draft, which may be enacted into law this year. The draft undertakes, for the first time in Austria, to define medical activities the exercise of which is expressly reserved to legally qualified persons. Furthermore the requirements for the practice of medicine are stated, and provisions for the revocation of the right to practice are established. The following provision is entirely new. So long as the studies and the examinations prescribed for the attaining of a doctor's degree in medicine do not provide for practical training for newly graduated physicians, such a course of training for the physician extending over at least one year, at the bedside of patients, after obtaining a doctor's degree, must be evidenced by acceptable certificate before such a physician can begin to practice. The draft recognizes furthermore the principle that the license to practice is not bestowed by a board but results automatically as soon as the requirements (studies and examinations) have been met. Confirmation, by authorities of the license serves only the purpose of general control, in order to prevent unauthorized persons from practicing. The authorities as in the past, will not be permitted to interfere with the professional activities of physicians. Only in exceptional cases (for instance, sudden onset of mental disease in a physician), which might endanger public welfare, can the authorities intervene or forbid the activities of the physician. A permanent prohibition to practice will, however, require a judicial investigation in cooperation with the chamber of physicians. The protection of physicians against damage to their profession is strengthened by the fact that the title "physician" or "doctor of medicine" is legally protected. Migratory practice—practicing simultaneously in two or more different communities or in two or more different places of the same community—is absolutely prohibited. Likewise, the title of "specialist" is legally restricted. The disciplinary powers of the council on medical ethics, which is to be appointed by the chamber of physicians are strengthened. As compared with previous provisions, much heavier fines for offenses against the tenets of medical ethics are impossible. More particularly, the draft of the proposed legislation provides that in grave offenses, the council on medical ethics may deprive the guilty physician of the right to practice. Such a decision may on appeal be reversed by the ministry of public health. Medical circles are protesting against this provision of the draft which would enable a physician's colleagues to impose on him what would amount to a death sentence. It may be assumed that the universal rejection of this particular paragraph will induce the government to strike it out. The proposed law provides that for the practice of medicine in Austria the following conditions must be met: (1) citizenship of Austria; (2) a diploma granted by a faculty of medicine in Austria or a similar diploma bestowed by a foreign country and approved by competent authorities in Austria; (3) practical training for at least one year in a hospital after attaining of the diploma of doctor of medicine; and (4) attainment of full legal age which in Austria is 24 years. An interesting provision of the projected law is that a physician who practices medicine shall pursue no other occupation that is inconsistent with the dignity and honor of the medical profes-

sion. No physician may refuse to give necessary first aid unless he has a convincing reason for such refusal. Nor may a physician who has been elected a member of the chamber of physicians (the legal representative body of the medical profession) refuse to serve in such a capacity unless he can present acceptable reasons. Another provision is an effort to check the entrance of undue numbers to the medical profession. The admission of physicians to service in the *kranken-kassen* is to be regulated in such a manner that only such physicians will be accepted as have had at least two years of hospital experience and have been for at least ten years citizens of Austria.

Mortality from Tuberculosis in Vienna

The Statistical Yearbook of the city of Vienna for 1932 states that the number of persons who died in 1931 from all forms of tuberculosis was 3,158 whereas the number in 1932 was reduced to 2,804. The mortality of tuberculosis was 19 per 10,000 of population during the five-year period 1926-1930, 17 in 1931, and only 15 in 1932. This marked decrease is doubtless due to the excellent housing facilities in Vienna. The municipality of Vienna has erected 30,000 dwellings (about 10 per cent of the total number in Vienna), all of which are constructed in accordance with modern, hygienic principles. These dwellings have been placed at the disposal of the poorer strata of the population at a low rent. This generous housing policy of the municipality has thus discovered the most effective means of combating the tuberculosis morbidity and also the tuberculosis mortality.

Marriages

THOMAS ENGLISH McGEACHY, Decatur, Ga., to Miss Frances Josephine Fletcher of Winston-Salem, N. C., August 2.

OSCAR DAVID GARVIN, JR., Ridge Spring, S. C., to Miss Evelyn Margaret Williamson of Columbia, in August.

EDWARD BRUCE MEWBORNE, Lawrenceville, N. J., to Miss John Zennie Alridge of Thomasville, Ga., June 24.

JOSEPH CHARLES TATUM, Ancon, Canal Zone, to Miss Evelyn Katherine Locher of Memphis, Tenn., August 4.

WILLIAM LAWRENCE MATTISON, Calvin, Okla., to Miss Lois Juanita Martindale of Nashville, Ark., June 26.

BERNARD PATMOS, Adrian, Mich., to Miss Frances Elisabeth Hyde of Evanston, Ill., September 30.

OSCAR HENRY HANSON, Cambridge, Wis., to Miss Helen Jean Young of Fort Atkinson, August 16.

THOMAS HENRY BLAKE, Sheffield, Ala., to Miss Laura Lee Peaster of Thornton, Miss., August 2.

DEWITT TALMADGE MILAM, Monroe, La., to Miss Mary Lee Beckett of Shreveport, August 1.

SIGMA VAN LEWIS, Middlesex, N. C., to Miss Ola Elizabeth Caudle of Randleman, August 5.

HENRY PARDEE CARR, Milledgeville, Ga., to Miss Marion Corrigan of Atlanta, August 23.

EDWARD DOTY DAKE, Rome, N. Y., to Miss Muriel Doris Stretton of Syracuse, April 19.

OLIVER W. JENKINS to Miss Mary Ellen Bailey, both of Chattahoochee, Fla., July 30.

WILLIAM F. MYERS, Coal Valley, Ill., to Miss La Verne Madison of Moline, June 28.

RAYMOND R. RIVARD, Madison, Wis., to Miss Edna Sinz of Fond du Lac, August 16.

DONALD M. NORTON, Medford, Wis., to Miss Anne Russell of Lake Geneva, in August.

ROBERT E. BURNS to DR. CHARLOTTE J. CALVERT, both of Madison, Wis., August 14.

LELAND J. BRANNON, Columbia, S. C., to Miss Viola Mobley of Kershaw, August 19.

LUCIUS GEORGE THOMAS, New Orleans, to Miss Julia Ruth Gray, August 6.

HUGH L. BASS to Miss Valeria Edelen, both of Louisville, Ky., in August.

Deaths

Henry Jackson Hayes ☉ Major, U S Army, retired, Memphis, Tenn., Medical College of Virginia, Richmond, 1914, member of the American Psychiatric Association, served during the World War, was appointed first lieutenant in the medical corps in 1919 and was retired as a captain in 1926 for disability in line of duty, was promoted major under an act of Congress in 1930, medical director of a sanatorium bearing his name, aged 44, died, September 15, of acute dilatation of the heart and influenza

Raymond Bartlett Morris ☉ Olean, N Y, Johns Hopkins University School of Medicine, Baltimore, 1910, secretary of the Cattaraugus County Medical Society, member of the American Roentgen Ray Society and the Radiological Society of North America, fellow of the American College of Surgeons, served during the World War, on the staff of the Olean General Hospital, aged 48, died, September 16, of myocarditis

Denis Edward McMahon, Elmhurst, N Y, University and Bellevue Hospital Medical College, New York, 1908, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, past president of the Queens County Medical Society, on the staffs of St Catherine's Hospital, Brooklyn, and St John's Long Island City Hospital, aged 49, died suddenly, September 8, of heart disease

Arthur Dermont Bush, Decatur, Ga., Atlanta College of Physicians and Surgeons, 1901, member of the Massachusetts Medical Society and the Medical Association of Georgia, formerly professor of pharmacology, Emory University School of Medicine, Atlanta, author of "A Text-Book of Pharmacology" and "College Text-Book of Physiology", aged 58, died, September 6, in Albany, of multiple sclerosis

Maurice Daniel Barnette, Watertown, N Y, University of Michigan Medical School, Ann Arbor 1912, member of the Medical Society of the State of New York, served during the World War, on the staffs of the House of the Good Samaritan and the Mercy Hospital, aged 46, died, September 7, of complications following an operation for appendicitis

Randall Solon Tilles ☉ St Louis Washington University School of Medicine St Louis, 1908, formerly instructor in obstetrics, St Louis University School of Medicine, served during the World War on the staffs of the Jewish and St Louis Maternity hospitals, aged 50, died, September 14, following an operation on the gallbladder

Thomas Meares Green ☉ Wilmington, N C, University of Maryland School of Medicine Baltimore, 1900, fellow of the American College of Surgeons, on the staffs of the Bullock and the James Walker Memorial hospitals, Wilmington and the Babies Hospital, Wrightsville Sound, aged 54, died, September 14, of myocarditis

James Alexander Browne, Paterson N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, formerly health officer, county coroner and registrar of vital statistics in Paterson on the staff of St Joseph's Hospital, aged 67, died, September 6, of carcinoma of the tongue

Parnell E. Fisher ☉ Providence, R I, College of Physicians and Surgeons, Medical Department of Columbia College, 1894 on the staffs of the Rhode Island, Providence Lyng-In Homeopathic and Miriam hospitals, aged 65, died, September 16 of cerebral thrombosis, diabetes mellitus and arteriosclerosis

Frederick Wooster Owen, Morristown, N J, Georgetown University School of Medicine, Washington, D C, 1867, member of the Medical Society of New Jersey formerly on the staffs of the All Souls Hospital and the Morristown Memorial Hospital, aged 92, died, August 25, of lobar pneumonia

Derostus E. Smith ☉ Kansas City, Kan. College of Physicians and Surgeons, Medical Department Kansas City University 1900, Kansas City Homeopathic Medical College, 1901, aged 56, on the staff of the Bethany Methodist Hospital, where he died, September 2, of coronary thrombosis

John K. Moradian, Chicago, National Medical University, Chicago 1897 College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1901 member of the Illinois State Medical Society aged 61 died August 13, of bronchopneumonia and myocarditis

Ulysses Morris Bachman, Cleveland Cleveland College of Physicians and Surgeons Medical Department Ohio Wesleyan

University, 1907, served during the World War, on the staff of the Polyclinic Hospital, aged 51, died, September 14, of subacute bacterial endocarditis

William George Miller ☉ Norristown, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1897, past president of the Montgomery County Medical Society, on the staff of the Montgomery Hospital, aged 59, died, September 6, of cerebral thrombosis

Frederick Hilliard Robinson, New Bedford, Mass., Tufts College Medical School, Boston, 1896, member of the Massachusetts Medical Society, aged 64, died, August 31, in the Huggins Hospital, Wolfeboro, N H., of strangulated hernia and diabetes mellitus

Edwin Ruthven Harvey, Long Beach, Calif., Eclectic Medical Institute, Cincinnati 1901 charter member of the board of directors and on the staff of the Seaside Hospital, aged 59, died, June 21, of a rupture of the esophagus into the left pleural cavity

James Aloysius McCracken, Norristown, Pa., Medical-Chirurgical College of Philadelphia, 1905, member of the Medical Society of the State of Pennsylvania served during the World War, aged 52, died, August 12, of injuries received in a fall

William Herbert Rothwell, Murray, Utah, Gross Medical College, Denver, 1900, member of the Utah State Medical Association, veteran of the Spanish-American War, formerly city health officer, aged 56, died, August 16, of carcinoma of the lung

Harold Albert Bachmann ☉ Chicago, University of Pennsylvania School of Medicine, Philadelphia 1917, member of the Central States Pediatric Society, on the staff of St Luke's Hospital, aged 41, died, September 21, of angina pectoris

John Gustavus Rulison ☉ Lansing Mich., University of Michigan Medical School, Ann Arbor 1903, served during the World War, member of the state legislature, aged 57, died, September 3 of coronary thrombosis

Rienzi R. Shank, Trotwood, Ohio, Medical College of Ohio Cincinnati, 1900, member of the Ohio State Medical Association, veteran of the Spanish-American War, aged 63, died, September 14 of heart disease

Burton O. Post, Sulphur Springs Ind., Medical College of Indiana, Indianapolis 1888, member of the Indiana State Medical Association for many years bank president, aged 69, died September 1, of heart disease

Samuel B. McKerrihan, Portsmouth, Ohio, Medical College of Ohio, Cincinnati 1877, member of the Ohio State Medical Association, aged 84, died, August 13, in the Mercy Hospital of prostatic hypertrophy

Walter Elliott Lauderale ☉ Geneseo N Y, College of Physicians and Surgeons Medical Department of Columbia College, New York, 1874, formerly mayor, aged 83, died August 28 of cerebral embolism

George Malcolm Anderson, Lincoln, Kan. College of Physicians and Surgeons Medical Department Kansas City University, 1901 member of the Kansas Medical Society, aged 60, hanged himself, June 30

Jesse Overton, Troup, Texas, Louisville (Ky.) Medical College, 1893 member of the State Medical Association of Texas health officer of Troup, aged 62, died, July 26 of carcinoma of the right lung

Harvey M. Griggs, Philadelphia, University of Maryland School of Medicine, Baltimore, 1890, aged 67, died August 20, in the Homeopathic Hospital, Reading, of injuries received in an automobile accident

Ledru Pierson Smock ☉ Haddonfield, N J, University of Pennsylvania School of Medicine Philadelphia, 1882, member of the Medical Society of the State of Pennsylvania, aged 76, died, September 14

Thomas Bernard Scott ☉ Seattle, John A. Creighton Medical College, Omaha, 1917, served during the World War, aged 42, died, August 17, in the Virginia Mason Hospital, of pulmonary tuberculosis

Frederick Symon Cate, Los Angeles University of Maryland School of Medicine, Baltimore, 1898, aged 72, died August 14 of chronic myocarditis, chronic arteriosclerosis and cirrhosis of the liver

Mason Allen, St Paul University of Minnesota Medical School Minneapolis 1897 member of the Minnesota State Medical Association, aged 60, died, August 31, of hypertensive heart disease

Arthur Allen Hugg, Middleport, Ohio, Jefferson Medical College of Philadelphia, 1883, member of the Ohio State Medical Association, aged 80, died, September 2, of cerebral hemorrhage

Arnold Frotcham Furrer @ Cleveland Harvard University Medical School, Boston, 1902 for many years member of the school board, aged 57, died, September 12, of coronary thrombosis

Homer Erwin Safford @ Detroit, University of Michigan Medical School Ann Arbor, 1896, member of the American Psychiatric Association, aged 63 died September 12, of hypernephroma

Andrew Hunter Sullivan, Sulphur, Okla (licensed, Oklahoma, under the act of 1908), member of the Oklahoma State Medical Association, aged 59 died, July 24 of heart disease

James Claude Paine, Peoria Ill, Northwestern University Medical School, Chicago 1898 served during the World War aged 58, died August 17, of a self-inflicted bullet wound

Alexis B Barker, Peoria Ill Cincinnati College of Medicine and Surgery, 1892 member of the Illinois State Medical Society aged 58 died September 10, of pulmonary tuberculosis

Robert Erskine, Lowellville, Ohio, Kentucky School of Medicine Louisville, 1898 formerly mayor of Lowellville, aged 79, died suddenly, August 30, of cerebral hemorrhage

Theodore Barrington David, Indianapolis, Indiana University School of Medicine Indianapolis, 1929, aged 28, was found dead August 21, of a self-inflicted bullet wound

Francis Edward Chalmers, George, Iowa University of Toronto Faculty of Medicine Toronto, Ont, Canada, 1904, aged 58, died August 1, of carcinoma of the pancreas

Augustus E Hewitt, Walnut, Kan, Rush Medical College, Chicago, 1889, also a druggist aged 73 died September 5, of cerebral hemorrhage and diabetes mellitus

Kate A Machin, Macomb, Ill Keokuk (Iowa) Medical College, 1898, member of the Illinois State Medical Society aged 72, died, August 6, of carcinoma of the liver

John Johnson Rufe @ High Bridge, N J, Jefferson Medical College of Philadelphia, 1902 aged 56, died, August 17 in the Easton (Pa) Hospital of septicaemia

Edwin George Wood, Carmel, Calif, McGill University Faculty of Medicine Montreal Que, Canada 1885, aged 72, died July 10, of coronary thrombosis

Napoleon J A Salvail, Helena, Mont School of Medicine and Surgery of Montreal Que, Canada, 1883, aged 73 died, August 19 of angina pectoris

Lambertus Kuntz Perry Okla Vanderbilt University School of Medicine, Nashville, Tenn 1893, aged 75, died, June 25 of cerebral hemorrhage

George Littleton Wilson, Banks, Ark Memphis (Tenn) Hospital Medical College, 1900 aged 63 died, May 8, in Houston, Texas of heart disease

Benjamin Wesley Toothaker @ St Joseph Mo, Kansas City Medical College 1900 aged 58 died, August 4 in Rochester, Minn, of pituitary tumor

Jefferson D Clemons, Coronado, Calif University of Louisville (Ky) School of Medicine 1892 aged 72, died, July 17 of chronic myocarditis

Samuel Miller, Des Moines, Iowa Drake University College of Medicine Des Moines 1912 aged 49 died, August 14 in the Mercy Hospital

Ernest H Muse @ Roanoke Va University College of Medicine Richmond 1907 aged 52 died, June 10 of cerebral edema and arteriosclerosis

Verlin C Thomas, San Francisco American College of Medicine and Surgery Chicago 1904 aged 57 died July 29 of coronary occlusion

James Buckner Lewis, Salem Ill Eclectic Medical Institute Cincinnati, 1878 aged 80 died August 29 of carcinoma of the prostate

L L Janeway, Whitewell Tenn Chattanooga Medical College 1892 aged 83 died May 15 of lobar pneumonia and a lup fracture

Amos E Calvert Parsons W Va Physio Medical College of Indiana Indianapolis 1884 aged 70 died August 17, of ascites

Noah S Nonamaker Mahone Bay N S Canada Jefferson Medical College of Philadelphia 1879 aged 79 died, May 24

Leo Blais Lac Megantic Que. Canada Laval University Faculty of Medicine Quebec 1904 aged 55 died July 10

Bureau of Investigation

HISTEEN

Another Addition to Asthma and Hay Fever Quackery

"Histeen" is a newcomer in the "patent medicine" field It is put on the market by the Histeen Corporation of Chicago According to the state records Joseph B Creevy is the president of the concern and also one of the three directors Creevy is no new name to the readers of this department of THE JOURNAL As has been brought out in other articles, Joseph Creevy some years ago was employed as an advertising man of a Chicago tailoring company and later employed as office manager of a general mail-order business Doubtless realizing that the chief asset in mail-order quackery is a knowledge of the mail-order business, plus a knowledge of advertising, and knowing how unnecessary it is to have any medical, chemical or pharmaceutical knowledge, Creevy went into the nostrum field What seems to have been his first 'patent medicine' concern was the 'Western Medical Association' (dealt with in THE JOURNAL, Jan 28, 1922), a crude piece of mail-order quackery which purported to sell to persons it never saw a treatment for epilepsy The name of the concern was later changed to "Western Medical Corporation" (the subject of an article in THE JOURNAL Aug 5, 1933), but Creevy continued to act as president

The next heard of Creevy was in connection with the Van Ard Sanatorium (dealt with in THE JOURNAL, April 19 1930), a piece of mail-order rheumatism-cure quackery Creevy was president and his brother-in-law H L Cassel, was secretary Cassel was also alleged to have formerly been employed by the same mail-order concern that employed Creevy Cassel, it appears, was also the sole owner of the Cass Laboratories (see THE JOURNAL Jan 15 1927) which, like the Van Ard outfit, sold a mail-order cure for rheumatism The secretary of the Van Ard Sanatorium at the time of its incorporation was one J A Carroll who is treasurer of the Histeen quackery and also connected with 'Witter Water,' a product advertised by "patent medicine" methods

The Histeen business and other Creevy quackeries are housed in a building at the corner of Canal Street and Purshing Road, Chicago One finds in the Chicago telephone directory the following concerns listed under the same telephone number and in the same building

WESTERN MEDICAL CORPORATION	VERNON MEDICAL COMPANY
H L CASS CORPORATION	RESEARCH PRODUCTS COMPANY
CHARLES J CAHILL M D	HISTEEN CORPORATION
WITTER WATER INC	

It should be said in explanation that Charles J Cahill, M D, was if he is not still, 'medical superintendent' of the Van Ard quackery, while the Vernon Medical Company is merely another name under which the epilepsy cure" is sent out

The advertising of Histeen first appeared about the middle of August, this year, and according to a large broadside that was sent out by the Histeen concern or its agents was to be featured in certain newspapers in the middle-west The broadside itself was a foot and a half wide by two feet long and it has been reduced to a few inches in the reproduction that appears with this article It was sent to druggists as an argument for them to "cash in" on the demand that the advertisements might be expected to create According to it, large display advertisements of Histeen were being carried in the following newspapers

Tribune Chicago	Commercial Appeal Danville Ill
Globe Democrat St Louis	Argus Rock Island Ill
Journal Transcript Peoria Ill	News Indianapolis
Register Republican Rockford Ill	Tribune South Bend Ind
State Journal Springfield Ill	News Sentinel Fort Wayne Ind
Herald Review Decatur Ill	Courier Journal Evansville Ind
Dispatch Moline Ill	Star Tribune Terre Haute Ind
Pantagraph Bloomington Ill	Star Muncie Ind
Democrat and Leader Times Davenport Iowa	

Those who are familiar with newspapers of the middle west will recognize that the papers listed above do not belong to the cheap and nasty type of publications but are of the responsible

and conservative class. This again verifies what is notorious to those familiar with the problem, namely, that the advertising ethics, by and large, of most newspapers and magazines is determined by the counting-house. When times are prosperous and advertising contracts for meritorious merchandise are comparatively easy to get, newspapers carefully scrutinize advertisements and reject much of the crude "patent medicine" copy offered. During financial depressions, with advertising incomes seriously threatened misleading and even fraudulent advertisements begin to appear in many of the best dailies published. A few years ago it was quite inconceivable that, for example, the *Chicago Tribune* a paper that has made a name for itself in fighting some forms of quackery, would accept an advertisement for such a product as Histeon, and the same is probably true of many of the other papers that are carrying Histeon advertising.

The Histeon advertising declares that hay-fever and pollen asthma are due to histamine poisoning and that Histeon is a compound which "acts to counteract histamine poisons, neutralize its action and release the irritating effect of histamine." The advertisements state further that the compound known as Histeon is the alleged discovery of a "Chicago specialist"—a "member of the American Medical Association"—who, after two and a half years of research evolved Histeon, and that his discovery has been verified by tests conducted in the laboratories of a famous medical university.

Photographic facsimile of label from bottle of Histeon

When the Histeon Corporation was asked to give the name of the "Chicago specialist" and the "famous medical university" it refused to do so on the ground that when it entered into negotiations with the "specialist," it "agreed to purchase his formula and transact business only with the understanding and agreement signed to that effect that we would not at any time divulge his name or the name of the university where the tests were made with the product." This, according to the Histeon Corporation, "is solely for the purpose of protecting this physician's ethical standing." One can dismiss the fact that it might be difficult to injure the "ethical standing" of a physician who would enter into an agreement of this kind and assume that the exploiters of Histeon are much too experienced in the field of quackery not to know that the chief asset of the nostrum exploiter is mystery based on secrecy.

From what has been said regarding the main thesis of the Histeon advertising, namely, that hay fever and pollen asthma are both due to histamine poisoning and that Histeon is supposed to be an antidote for it, one familiar with the research that has been done in this field would naturally assume that Histeon might be expected to carry as its chief ingredient some substance such as histaminase. Because of the large number of inquiries that have come in regarding this product, the Bureau of Investigation asked the Chemical Laboratory of the American Medical Association to have Histeon analyzed so that the findings could be presented to the medical profession and the public. The A M A Chemical Laboratory has not only done a large amount of chemical work on the product, but it reports on pharmacognostic and biologic investigations of the nostrum. The findings are incorporated in the report that follows.

LABORATORY REPORT

"Original specimens of Histeon (Histeon Corporation, 415-423 W 39th Street, Chicago) were submitted to the A M A Chemical Laboratory for examination at the request of the Bureau of Investigation. [A photographic facsimile of the label on the bottle appears on this page—LD.]

"The bottles of Histeon each contained 30 tablets of a gray color, possessing an aromatic odor. The average weight of a tablet was 0.42 Gm (approximately 6½ grains) with a variation of 2.8 per cent above to 1.5 per cent below.

"Qualitative tests indicated the presence of antipyrine, phenobarbital and ephedrine, a small amount of chloride, together with excipients such as starch, talc and calcium carbonate. The aqueous extract of Histeon was alkaline in reaction. Emodin-bearing drugs, acetylsalicylic acid, epinephrine, iodides and arsenic compounds were not found. Pharmacognostic examination indicated the presence of a small amount of powdered lobelia, but did not disclose stramonium.

"As the Histeon advertising gives the impression that this product contains histaminase, pharmacologic tests were made by an authority on this subject. He reported as follows:

Histaminase (the specific histamine inactivating enzyme) cannot be detected in the tablets. Histamine is not inactivated on sterile incubation with Histeon. Histaminase is an oxydase decomposing histamine with simultaneous consumption of oxygen. No oxygen uptake was observed when Histeon and histamine were kept under the proper conditions. Even if Histeon had contained a histaminase preparation it would probably be of no value when given by mouth because it would be destroyed by the stomach. Carefully prepared extracts from Histeon were dissolved in water adjusted to proper pH and were subjected to tests on smooth muscle. Contractions of dogs and guinea pigs intestine were produced with histamine and pilocarpine. Such contractions were very slowly relaxed by addition of the above Histeon extract (indicating the presence of a drug such as ephedrine). Antipyrine and phenobarbital were shown not to cause relaxation of the above contracted smooth muscles under the conditions of the experiment. Belladonna alkaloid (atropine) was not indicated.

"Quantitative determinations yielded the following:

Antipyrine	61.1 per cent
Phenobarbital	2.75 per cent
Ephedrine base	1.5 per cent

"Based upon the foregoing it may be calculated that Histeon tablets contain as essential ingredients: Antipyrine, approximately 60 per cent, phenobarbital (or phenobarbital sodium) approximately 2½ per cent and ephedrine, probably as ephedrine hydrochloride 1½ per cent. Each tablet, therefore, may be calculated to be equivalent to approximately:

Antipyrine	(0.257 Gm) 4 grains
Phenobarbital	(0.012 Gm) 0.2 grain
Ephedrine hydrochloride	(0.008 Gm) 0.12 grain

Based on the average daily dose (8 tablets) recommended, this would be equivalent to: Antipyrine, 32.0 grains, phenobarbital, 1.6 grains, and ephedrine hydrochloride, 1.0 grain. Furthermore, the firm states that "where necessary, 3 tablets per dose may be taken with perfect safety as long as required."

This represents a daily dose of 12 tablets which (based on the foregoing) would be equivalent to: Antipyrine 48 grains, phenobarbital, 2.4 grains and ephedrine hydrochloride 1.4 grains.

From the analytical work, it seems then, that this "amazing new direct relief" has for its chief ingredient, making up nearly 60 per cent of Histeon, our old friend antipyrine, which has been used by physicians for nearly fifty years and has been prescribed for the purpose of giving symptomatic relief in certain forms of asthma and hay fever for almost as long. In addition Histeon has also phenobarbital (luminal), as well as ephedrine a substance that enters into an enormous number of proprietary remedies for the symptomatic relief of hay fever and asthma. And this mixture of well known drugs is the alleged discovery of a "Chicago specialist" who will not allow his name to be used because he is afraid of hurting his "ethical standing."

But this is not all of the story. The trade package of Histeon recommends as dosage either two or three tablets four times a day. The statement is made that three tablets four times a day may be taken with perfect safety as long as required. Obviously from the analytical work done, the person who takes Histeon gets 4 grains of antipyrine with each tablet, and where he takes three tablets four times a day he has a daily intake of 48 grains of antipyrine! He also gets in the same period about 2½ grains of phenobarbital and about 1½ grains of ephedrine.

In view of this, the following facts are of interest (1) A Mr F, who lived in the Chicago area and who had for some time been a sufferer from asthma, started taking Histeon apparently about the time it first came on the market the middle of August On August 23 his family called in a physician, but Mr F was dead when the physician got there The death certificate gave as the direct cause of death acute dilatation of the heart, with bronchial asthma and hypertrophy of the heart as contributing causes

(2) A pharmacist in Milwaukee wrote in for information about Histeon and stated that a young woman who was suffering from hay fever had been using the nostrum, and added "It relieves the hay fever, but seems to make her sleep"

(3) A physician in northern Illinois reported that he had had many inquiries concerning Histeon and, being a sufferer

condition, as there is no evidence of nephritis or cardiac disease, nor could we trace the edema to any other cause"

On September 16 the officials intrusted with the enforcement of the National Food and Drugs Act seized 1,294 packages of Histeon in St Louis, Mo., charging that the stuff was misbranded under the federal law All that the quacks who exploit Histeon have to do, however, under our present inadequate law, is to cease making false, misleading or fraudulent claims on their *trade packages* and they will be exempt from the penalties of the Act They can falsify to their hearts' content in the newspaper advertisements on billboards over the radio, or in any other avenues of publicity that will help to sell their nostrum And the public will, in total ignorance, be persuaded to swallow this potentially dangerous mixture in the belief that a new cure has been discovered and that it is quite safe!

Summed up then, it seems that, essentially Histeon is a secret mixture of three well-known drugs, all of them potentially dangerous in the hands of the untrained Further the nostrum is recommended in dosages that a physician with any regard for his patient's safety and his own reputation would hesitate to prescribe

Correspondence

HEAT PROSTRATION AND DEHYDRATION

To the Editor—Two years ago, as I heard the story of a friend who collapsed after hours in his orange grove on an intensely hot day, it occurred to me that heat exhaustion is dehydration He was brought back to practically normal by 1,000 cc of dextrose salt solution in the half hour it took to give it THE JOURNAL published my report, Oct 17, 1931, p 1169

My suggestion a little later to Dr Ray Lyman Wilbur, then Secretary of the Interior that Hoover Dam would be a good place to test this principle resulted in Dr W A Haas and the officials of the Six Companies interesting themselves in it and establishing the necessary plant and in Harvard University sending a research group to the dam in the summer of 1932

In April 1932 I visited Hoover Dam and discussed prevention and treatment of heat exhaustion with Dr W A Haas, then in charge Abundant good drinking water was then being provided During that summer the use of abundant water both in prevention and in treatment was followed Unfortunately, Dr Haas died in March, 1933, but his successor, Dr R O Schofield has followed the same plans this summer

After the pioneer stage of crude facilities with its disastrous record of 1931, two simple preventive measures were adopted The first was an adequate, palatable, easily accessible supply of good drinking water Next was the blanket advice to every one to drink freely—more than enough

During a part of July and August, 1932, a group of investigators came from Harvard University, under the leadership of Dr D P Dill for the purpose of studying especially the question of fatigue in high temperatures The result of their work was to emphasize the importance of keeping up the supply of chlorides and the blanket advice that every one should take an abundance of table salt with meals or otherwise

The Six Companies having the contract for building the dam together with the insurance carrier give the employees excellent hygienic care They have established three first aid stations with personnel in addition to the hospital Weekly first aid and educational meetings are held and at the meetings these heat protective measures have been fully discussed, so that the men are well informed on the general program and especially on the use of water in large quantities at all times The emphasis has been less on salt but more on water It should of course be on both Great care is given the water supply, so much so that they did not hesitate to import water

HISTEON

Miniature reproduction of a broadside to druggists telling them about the heavy advertising campaign of Histeon In the original this was 1 1/2 feet wide and 2 feet high

from hay fever himself, he took some of the nostrum He describes the physiological reaction thus

"I took three tablets within a period of six hours which is a much smaller dose than recommended by the directions It had quite definite physiological results I am convinced that it contains ephedrine or some adrenalin-like substance It did stop the hay fever symptoms and seemed to raise the blood pressure and increase the pulse rate It also had an adrenalin reaction in that there was apparently a dilatation of the kidney capillaries as shown by marked increase in the amount of urine The skin seemed quite dry and there was also quite definite dryness of throat especially of soft palate My impression is that this preparation is definitely a dangerous preparation to give to the public My own reaction was a feeling that I did not dare take much more of it"

(4) A Chicago physician sends in the following report
Mr L 26 years old, was persuaded to try this remedy [Histeon] for hay fever On September 6 he took as directed two tablets after each meal and two next morning About two that afternoon he became ill nauseated vomited twice, and soon began to have a severe angio-neurotic edema of the penis testicles both hands and both feet He is still unable to walk It is very probable that Histeon is directly responsible for his

from Las Vegas, 30 miles away, when their own supply from the Colorado was temporarily unpalatable. At the hospital, preparations are at hand to give immediate intravenous and subcutaneous salt and dextrose solutions in acute cases of heat exhaustion. The result of this treatment, which was carried out in all cases both in 1932 and in 1933, has been most gratifying—prompt improvement and prompt recovery in all cases. A record of the 1932 cases is found in "Heat Cramps: A Clinical and Chemical Study" by John H. Talbott and Jost Michelsen (*J. Clin. Investigation* 12:533 [May] 1933). The results are a veritable laboratory demonstration. In the face of an excessively hot summer with scores of cases all over the country, the Hoover Dam community, though situated in an area of extremely high summer temperatures, has been practically exempt. The record 1931, seventeen deaths from heat exhaustion, no record of number of recoveries 1932, no deaths, seven mild cases of exhaustion, all patients recovering promptly 1933, no deaths, four cases of exhaustion, all patients recovering promptly.

Mr. H. C. Watts, superintendent of the substation of the Southern Sierras Power Company at Hoover Dam gives the following data on temperatures for approximately six weeks during July and August, 1933: average maximum, 108, average minimum 90, high range, 126, average humidity, 50 per cent. These temperatures were taken in the usual government official housing. They were taken on the upper dam levels from 700 to 800 feet above the bed of the river. Temperatures in the bottom of the river canyon, where much of the work is going on, are normally about 10 degrees higher than on the cliffs where these thermometers are located.

The plan of treatment is built on the principle that heat exhaustion is dehydration with loss of chlorides. A day on the desert demonstrates that the 3 or 4 quarts of water taken leaves the body by transpiration visible or invisible, and a taste of the skin shows that it takes the chlorides with it. The salty taste of the arms caused a sensation in a group crossing the desert the other day. In high temperatures the body cools only by evaporation. Water passing from a solid to a vapor needs heat. This it takes from the body and thereby cools it. It may be in invisible quantities and the person may not show any perspiration but after a few hours careful weighing and the record of intake and output shows the enormous loss of water.

Dr. Dill in his experiments (*J. Biol. Chem.* 100:755 [May] 1933) lost 20 pounds in seven hours exercise covering a 20 mile walk in a shade temperature of 104 F. He made up a part of that by drinking 13 pounds of water meanwhile, leaving a net loss of about 7 pounds.

Autopsy records show an empty heart and a congested skin after sudden death from heat exhaustion and sunstroke. Evidently heat dilates the capillaries in the skin and allows outpouring of water from the body until there is not enough fluid left to fill the blood vessels sufficiently to keep up pressure in the brain. When the blood pressure drops below 70, 60 or 50 unconsciousness follows. The reserve intracellular and intercellular fluid is unavailable or too slowly available and for this the loss of chlorides is partly responsible by disturbing the osmotic balance. The cyanotic purple look of a victim of heat exhaustion has kept observers from seeing that the patient really has not enough water (blood) rather than too much and in need of bleeding, as was the custom not so long ago.

Early in 1932 the Southern Sierras Power Company broadcast the information to its employees, and though many of them have been working in desert and heat they have had no heat exhaustions during either 1932 a comparatively cool summer or 1933 an exceptionally hot summer.

CORNELIUS VAN ZWALENBURG, M.D., Riverside, Calif.

MILK AND MOLASSES ENEMA

To the Editor—In *THE JOURNAL*, recently, inquiries were made regarding the possible origin of the use of the milk and molasses enema. One of these letters states that Dr. Senn over forty years ago found in his investigations that it was in common use in India and possibly its first employment originated there.

My own professional work dates to early 1883. The three previous years, while a student, I had the privilege of riding with my grandfather, a physician of wide experience, over a large country field. I found him at that time using this formula frequently and I recall his stating to me that it was an old and valuable therapeutic measure.

I have no knowledge of it beyond this. He was educated in the Yale University Medical School, graduating about 1834. Something like twenty years ago two surgeons in the Mountain Side Hospital began using the milk and molasses enema in their professional work and seemed to think that they had found something entirely new. But when I recounted to them my experience of many previous years and where my knowledge of it came from they concluded that perhaps there was nothing new under the sun after all.

LESLIE W. HALSEY, M.D., Montclair, N. J.

PRECIPITATION TESTS FOR SYPHILIS

To the Editor—In an article in *THE JOURNAL*, August 12, page 542, Dr. Israel Weinstein presents his view of the history of the scientific development of the precipitation tests for syphilis. He apparently discovered an official confirmation of my priority in that part of medical science in the exhibit of the United States Public Health Service at the Chicago Century of Progress Exposition. He gives a list of scientists who published descriptions of precipitation tests for syphilis before I did in 1917. But he forgets to add that those tests never were approved of as reliable in practical laboratory work. None of my predecessors were able to get results of practical value with their methods. My reaction, the description of which was published in 1917, was the first one that proved to be of practical value. That is the main point. I was the first to show that it is possible to perform a precipitation test for syphilis of the same reliability as the complement fixation test of Wassermann.

The authors mentioned by Dr. Weinstein—Michaelis, Jacobsthal, Bruck, Hidaka and Hecht—never at all claimed priority against my methods. In all scientific books about precipitation tests even in the one written by Jacobsthal himself, will be found the confirmation of my priority in that field of science.

Dr. Weinstein criticizes the fact that I improved my methods during the course of time and presented several reactions, whereas Kahn in America worked out only one. The Kahn test was proved to be the best at the conference in Copenhagen and even better than my last reaction, the clarification test, at the conference at Montevideo. Dr. Weinstein forgets to add that Kahn himself executed his own method at that last conference whereas my reaction was performed by other scientists whom I do not know personally and who did not learn the method from me. Kahn himself in absolute loyalty laid stress on that important point in his review of the conference at Montevideo. Thus the question which of the two tests (Kahn test or clarification test) is really the better is not yet settled. Dr. Weinstein obviously thinks that the fact that an author for instance Kahn never altered his method proves that his method is absolutely perfect and does not need any improvement. That is an error. On the contrary, the same fact may be caused by the impossibility of improving the method. Every body knows that I am the last one to deny the great value of the Kahn test but like all the biologic methods even that

excellent test seems to have besides its well known advantages also some disadvantages in comparison with other methods. In some articles published in American medical journals I find complaints about the difficult reading of weakly positive Kahn reactions and about the instability of the antigens. With cerebrospinal fluids the Kahn test seems to be more complicated than other methods. If I were the author of the Kahn test I would try to alter those weak points of the method if it is possible. I do not know whether even Kahn himself would be able to do so if he wished to, for in all the biologic methods there is a certain limit of efficiency that cannot be passed over by technical improvements. Therefore the fact that a certain method was never altered by its author does not prove that it is absolutely perfect and does not need any improvement. As far as I know, Kahn himself never claimed the absolute perfection of his test.

BLOOD CELL COUNTING TECHNIC

To the Editor—In making a white or red blood cell count how much difference in the counting in each of the four corners do you consider a good count? The number of cells in each corner will vary in all counts and I should like to know the average difference. When Wright's blood stain is used will a longer time in using the stain undiluted or in using it after it is diluted with water bring out the polymorphonuclears and other cells more distinctly? Which part of the staining process brings out the polymorphonuclears? In making up a solution with tablets and methyl alcohol I find that there is much precipitate when the water is added when using it for staining. What is wrong? There are many variations in the technic of staining with Wright's stain and I should like to know which is considered the best one. Kindly omit name.

M.D. Minnesota

ANSWER—An accurate red or white blood cell count can be made only with an accurate hemocytometer, such as the Levy, which is the best obtainable. The cover glass must also be accurate and specially made for blood counting apparatus. The apparatus must be dry and clean, free from dust or lint. The diluting pipets must be accurate and preferably tested by the Bureau of Standards.

After the dilutions have been made the pipet should be shaken for at least two minutes and the first two drops discarded. Then the central platform should be filled with blood. If any air bubbles are present or liquid overflows into the grooves of the slide another mount should be made. The cells should be allowed to settle for three minutes. Low power is used in examining for uniformity of distribution. If the cells are unevenly distributed the diluted blood should be shaken thoroughly and the mount repeated.

At least 100 small squares should be counted. For accurate work 200 are recommended. Each twenty-five squares should be added separately. The highest and lowest totals should not vary by more than 25. Greater variations indicate poor mixing and necessitate repetition of the work. Osgood and Haskins Laboratory Diagnosis (Philadelphia, P. Blakiston's Son & Co. 1931) gives an excellent discussion of the technic of accurate blood counting.

The precautions for the white cell count are the same as given for the red cells. The four large squares (each 1 sq mm in area and containing sixteen medium sized squares) at the corners of the ruled area are counted.

The essentials of good staining with Wright's stain are a good blood smear and a good stain. If the stain is purchased in tablet form one tablet should be ground up in 10 cc of absolute anhydrous methyl alcohol (one tablet is 0.05 Gm.). The mixture is shaken and allowed to stand twenty-four hours and should be filtered before use. A fresh stain should be made at least once a month and filtered as often as a precipitate forms. The stain must be well stoppered to prevent evaporation of alcohol or the taking up of moisture.

The slide is covered with the stain and allowed to stand for one minute. During this minute the methyl alcohol fixes the

cells. Then an equal amount (same number of drops) of distilled water is added. Osgood and Haskins recommend a buffer phosphate solution instead of water (663 Gm of Merck monopotassium phosphate and 256 Gm of Merck anhydrous disodium phosphate in 1 liter of distilled water, 1 cc of chloroform being added). The time for the water or buffer solution varies with the stain, and the optimum must be determined by trial. This is usually one minute but may be as high as three minutes. Old stains require a longer time. When the time is up, the stains should not be poured off but floated off with water, the slide being held level. The slide should be washed thoroughly from half a minute to a minute. The slide should be placed on end to dry in the air.

The white cells should show distinct characteristic granules. If these do not show or are pale, and if the neutrophil granules are pink instead of lilac the fault is due to too short staining and the time must be increased. Poor differentiation may be due to too short a time of washing.

There should be no precipitate or debris on the slide. A precipitate will result from the use of a stain that needs filtering but is more often due to using too small an amount of Wright's stain permitting the methyl alcohol to evaporate almost completely before the water or buffer is added. It may also be due to pouring off the stain instead of floating it off and to insufficient washing.

USE OF METAPHEN IN PEPTIC ULCER

To the Editor—Dr. Clarence M. Trippe (*Ann Int Med* 6:901 [Jan.] 1933) has discussed in some detail the oral administration of metaphen in the treatment of gastric ulcer, duodenal ulcer and chronic ulcerative colitis. The author gives an average dose of 3 cc of 1:500 solution of metaphen and reports most gratifying results in eighty-two patients. In view of the fact that metaphen belongs to the nitrobenzene mercury complex would one be apt to produce severe renal damage from the oral administration of such a preparation? Would you consider this a safe therapeutic agent in obstinate cases not doing well under a strict Sippy regimen? Please omit name.

M.D. Indiana

ANSWER—P. J. Crittenden has investigated the action of metaphen, given intravenously, on the blood pressure, heart rate, respiratory rate, red cell fragility, and kidneys of dogs (*J Pharmacol & Exper Therap* 44:423 [April], 1933) and reports that the dosages recommended for intravenous use in man, 0.05 mg per kilogram, do not produce ill effects. As much as 1 mg per kilogram given intravenously for a long period did not produce any demonstrable changes in the kidneys. The lethal dose in rabbits and dogs varies between 3 and 5 mg per kilogram.

When given by mouth, the same precautions must be observed as for any other mercurial compound, considering the fact that metaphen has a mercury content of from 56 to 57 per cent. The daily administration of 16 cc of a 1:500 solution, which corresponds to 32 mg of metaphen and approximately 17 mg of mercury, for an unlimited time without a check on the urine is not without some danger despite the small amounts absorbed. The experiments of C. M. Trippe on the oral administration of metaphen to rabbits as described in his article do not give sufficient details from which definite conclusions can be drawn. At best this method of treatment is still in its experimental phase and its use should be restricted to patients who can be carefully checked for evidence of mercury poisoning.

BATH URTICARIA—UNUSUAL PIGMENTATION OF FACE

To the Editor—A girl aged 19 whose general physical condition is normal has a tendency to a bath urticaria. Immediately after a cold bath or swim she develops an intense itching all over the body. A hot bath or other external heat is the only means of relief. Will you give any information and the bibliography on this subject? Another girl aged 20 is developing pigmentation of the face closely simulating the mark of pregnancy. What remedies can you suggest for this disfiguring ailment? Please omit name.

M.D. Florida

ANSWER—Urticaria from cold, congelation urticaria, has been given considerable notice in recent years. Lehner in his case (*Klin Wchenschr* 8:306 [Feb. 12] 1929) demonstrated the presence in the blood serum of the part exposed to cold a substance which caused a wheal when injected into the skin of the patient or of other persons and in the healthy persons sensitized the spot injected so that it reacted to cold with wheal formation the Prausnitz-Küster reaction. By exposing to cold an arm in which the circulation of blood was cut off by a constrictor he showed that the irritating substance appeared only in the serum from the part exposed to cold. Serum from the other arm caused no reaction.

By applying an ice pack to the chest before breakfast, he caused a hemoclastic crisis during which the venous blood was cherry red and the white blood count only half that taken before the crisis with increase of polymorphonuclears and

decrease of lymphocytes. The refractometric index, 13480 before the crisis, was 13470 after it and the coagulation time was increased from four to five minutes. After two such shocks on succeeding days, the sensitization began to decrease and by persistent daily shocks was reduced nearly to normal in two months.

Perutz, Brugel and Grunfeld (*Klin Wchnsch* 8 1999 [Oct 22] 1929) reported failure to find any evidence that the disease is allergic in nature, but a number of other observers have reported results agreeing with those of Lehner (Weissenbach, R. J., and Brisset, J. P. *Ann de med* 32 233 [Nov.] 1932 Klein, A. E. *Dermat Wchnsch* 95 1741 [Dec. 3] 1932 Vallery-Radot, Pasteur, and Blamoutier, P. *Bull et mem Soc med d hop de Paris* 47 1907 [Dec. 21] 1931).

The girl with pigmentation of the face should be questioned on the use of any toilet water, such as cologne water, or perfume on her face before going into the sun (Lane, J. E., and Strauss, M. J. *Toilet Water Dermatitis* *THE JOURNAL* Sept. 6 1930 p. 717 Gross, Paul, and Robinson, L. B. *Berlock Dermatitis Unusual Dermatitis and Pigmentation Following the Use of Perfume* *Arch Dermat & Syph* 21 637 [April] 1930). She should be asked also whether she has used any preparation for the removal of freckles. While the pigmentation without preceding inflammatory patches is not typical the question of the use of phenolphthalein should be investigated.

If the pigmentation is about the mouth, erythrose peribuccale pigmentaire of Brocq must be considered, a vascular disturbance with pigmentary changes in women manifesting vascular instability and in most cases some definite pelvic disturbance (Ormsby, O. S., and Ebert, M. *Erythrose Pigmentaire Peribuccale de Brocq*, *Arch Dermat & Syph* 23 429 [March] 1931 Obermayer, M. E. and Becker, S. W. *Erythrose Peribuccale Pigmentaire de Brocq*, *ibid* 26 444 [Sept.] 1932).

The possibility of Addison's disease or hyperthyroidism must be considered, though it is unlikely that either of these conditions is present.

If no etiologic factor can be discovered and removed with benefit, the peeling treatment may be tried, with full knowledge that any agent which causes peeling may produce a recurrence of the pigmentation. The application might be tried twice daily of bismuth subchloride, 3 Gm., hydrogen dioxide, 10 cc. wool fat and petrolatum to make 30 Gm. until exfoliation occurs, then waiting to see the result and repeating if necessary.

LOW BLOOD PRESSURE IN PREGNANCY

To the Editor—A primipara aged 22 Caucasian whose father died at 50 of influenza and pneumonia but whose mother is living and well was somewhat anemic. The mother had several children without any troubles in delivery. The chest circumference of the patient Jan. 5 1933 was 75 77 and 79 cm. the last is full expansion. The pulse was 96 sitting. There was no elevation of temperature. The weight was 96½ pounds (43 7 Kg.) the maximum pelvic circumference 82 cm. The pelvic measurements were spines 22 cm. crests 24 5 cm. trochanters 30 cm. external conjugate 18 5 cm. I gave orders for a hematim in addition to the usual care. The blood pressure was 116 systolic 60 diastolic. She ate little as she was homesick and her family was far distant. I suspected a tuberculous area in the left chest. She was of the pale black-haired aquiline-nosed slender type with easily observed subcutaneous veins often seen in southern Jewesses. She is not Jewish. She was nervous and irritable. Under care every two weeks the chest condition improved rapidly and in two months nothing abnormal could be found. Her health and general condition went up nicely. Her appetite improved. She has had no dental trouble as I have seen that she has an adequate calcium diet. Her nervousness grew worse until I gave her a sedative she feels fine now. Her weight remained nearly stationary being 99 pounds (45 Kg.) Feb. 18 103 pounds (46 7 Kg.) April 4 109 pounds (49 4 Kg.) May 18 112 pounds (50 8 Kg.) June 27 and 116 pounds (52 6 Kg.) July 6 and for the first time she had a protruding abdomen. But her blood pressure since January 26 has been very low. At that time it was 94/76 June 27 it reached 96/72 and it has varied somewhat in between. This has caused me some anxiety and I am wondering just how dangerous such a small pulse pressure may be. The fetus seems to have developed normally the heart tones being between 120 and 144. The position seems to be left occiputransverse consistently. The urine has been invariably negative to both chemical and microscopic examination. The breasts are developing nicely. The last period occurred Nov. 8 1932. I estimated the fetus at about 4½ pounds (2 150 Gm.) June 27. Do you think the pelvis will interfere with delivery? Is this low blood pressure dangerous? The patient is due between July 20 and August 15. What troubles do you expect I will have if any and what management would you advise? I advised hospital delivery. She wants rectal anesthesia. M. D. Washington

ANSWER—No real trouble need be anticipated in this case. The low blood pressures recorded are not unusual in pregnant women because there is generally a drop of from 5 to 10 points during gestation. If the blood pressure goes below 90 however, the patient should be made to rest at frequent intervals. She should be given tonics, halibut liver oil with vosterol more calcium and abundant milk, fresh fruits and vegetables. If she is still anemic, active treatment should be directed to over-

come this also. If the baby is as small as estimated, there will most probably be no difficulty in spite of the fact that the pelvis is small. The patient should, of course, be given a test of labor. It is unfortunate that the diagonal conjugate measurement was not made because this is much more important than the external measurements. This measurement should now be made but under strictly sterile precautions, because delivery is due about August 15. The decision to have the patient in a hospital is a wise one, because all primiparas especially those in whom there are defects, should be delivered in a hospital. There is no reason why the patient should not be given rectal analgesia if she desires it unless, of course there are abnormalities in the rectum which contraindicate its use.

AMENORRHEA

To the Editor—I have a patient aged 18 who has not menstruated for six months. She began her menstrual period when she was 13 but it was never regular coming every two three or four months and now since December 1932 she has had no sign at all. She is a perfectly normal girl and has just completed her high school education. She has gained about 10 or 15 pounds during the last six months. I have given her whole ovary substance by mouth 5 grains (0 3 Gm.) three times a day for fifteen days with no results. Then I gave her six ampules of whole ovary hypodermically at two day intervals with no results. I have thought of dilating the cervix but because of her previous menstruation I did not think it necessary. What would you advise me to do? Please omit name. M. D. California.

ANSWER—The absence of menstruation is not necessarily an indication that treatment must be instituted to bring about a return of the menstrual function. However, since the patient is young and since she has gained in weight during the period of amenorrhea it is advisable to give her thyroid extract. This will have a much greater tendency to restore the menstrual flow than the ovarian preparations that have thus far been administered. The control of menstruation does not reside in the ovaries but in the pituitary gland. However, the thyroid gland has a definite effect on intense bleeding and thyroid extract given by mouth frequently, has a beneficial effect in cases of disturbed menstrual function. Of course, the patient must be watched closely while she is taking thyroid and it is wise first to have a basal metabolism test performed. If the rate is lower than normal there is an added indication for the use of thyroid but even if the rate is normal these preparations should be given. The Council on Pharmacy and Chemistry omitted from N. N. R. all whole ovarian preparations because there is no satisfactory evidence that they are active when given by mouth, nor is there evidence to justify their use by parenteral administration. The female sex "hormones" such as "Theelin" belong to a class of active principles, unlike the former in that they possess activity, but their therapeutic usefulness has not been placed on an established basis. In this connection reference is made to the Report of the Council on Estrogenic Substances Theelin, *THE JOURNAL*, April 29, page 1331.

INDUSTRIAL HAZARDS OF WORKERS WITH HARD RUBBER PLATES

To the Editor—I have a patient who does engraving and the cutting of rubber plates. He has become ill with nausea and dizziness whenever he goes round his place of work. He has been ill for several months. He is also troubled with cramping in the abdomen and aching in joints and muscles. His blood shows stippled red cells but he maintains that there is no lead around his work. Please advise what other type of poisoning such a patient may have from working with rubber and ink.

R. B. ROBINS, M. D. Camden, Ark.

ANSWER—It is assumed that this workman's duties involve only exposure to hard rubber plates and the substances ancillary to this work. Lead is little used in hard rubber and especially is likely to be absent from light colored rubber. Nevertheless it may be the cause of the disease state. The rubber should be tested for lead.

Antimony may be present. In the engraving process, antimony dust may be evolved and breathed. An increasing amount of attention is being paid to antimony as an industrial hazard. Gastro intestinal involvement is a prime manifestation. Should this workman use in his trade cleansing or softening agents such as benzene, naphtha or carbon tetrachloride, or similar agents much used in the compounding of rubber, the disorder, if occupational in origin may be traced to one or more of these substances. Should the information here furnished not be sufficient additional data as to the exact substances used at work should be compiled and sent for supplemental advice.

The fact that the workman becomes ill on merely going about the work place suggests the ill defined state related to sensitivity to naphtha or benzene occasionally encountered in industry.

CAUSES OF PIGMENTATION

To the Editor—A white child 9½ years of age has acquired in the past four years following a severe case of chickenpox, a mottled heavy brown pigmentation over the exposed portions of the body. It is worse on the dorsal than on the ventral surfaces of the arms. It is sharply demarcated around the neck, corresponding to the cut of the child's dress. The same description applies to the area protected by the shoes. The pigmentation is present on the mucous membranes of the mouth. She has had a few dizzy spells before breakfast but no undue fatigue or asthenia. She is gaining weight normally. There is no evidence of tuberculosis. The diet has been adequate in protein and vitamins. The pigmentation is increased by the sun. Salicylic acid ointment was applied to a small pigmented area on the skin until all superficial epithelium was denuded without effect on the pigmentation. The child's muscle tone is excellent. The appendages of the skin are normal. She is of average height and weight for her age. The blood pressure is 100 systolic 50 diastolic. The basal metabolism is plus 2. The urine is completely negative for sugar and albumin but a few pus cells are present. Is there any reason to believe that this pigmentation will be helped by injections of extract of the suprarenal cortex? What treatment would you suggest? Kindly omit name. MD Louisiana

ANSWER—It would be of interest to know what if any local applications have been made to the skin and whether the child was given sun or artificial light baths. Mercury preparations sometimes cause pigmentation and certain perfumes are capable of causing pigmentations if their use is followed by exposure to strong light. For such pigmentary changes to remain for four years, there would have to be repeated use. Was the child given arsenic for any length of time? Some persons react to a comparatively small amount. Have silver solutions been used in the nose and throat? The pigmentation of argyria is slate blue, however.

If all these possibilities can be excluded the glands of internal secretion, the ovaries, thyroid, pituitary or suprarenal cortex, may be suspected. The presence of pigment on the mucous membrane suggests the latter. The changes in these glands associated with puberty may correct the condition or experimental treatment with gland extracts may be tried. This seems justifiable if done cautiously.

UNUSUAL DISLOCATION OF ULNA

To the Editor—Would you kindly advise as to the frequency of a forward dislocation of the distal radio-ulnar articulation as a complication of Colles's fracture of the wrist? In a simple Colles fracture with slight backward displacement of the distal fragment and no impaction this complication seemed to occur. The reduction was easily obtained and checked by roentgenogram following application of a molded plaster splint. One week later massage and baking were instituted. Two weeks following the injury the distal extremity of the ulna was unusually prominent in front of the wrist and the prominence due to the styloid process was absent. This condition persisted after good union of the fracture and seriously interfered with flexion of the hand also causing numbness. Temporary relief is obtained by using a wrist support exerting pressure over the lower extremity of the ulna by means of a rubber pad. What treatment is indicated to restore permanent function? Please omit name. MD Washington

ANSWER—The unusually prominent dislocation of the ulna was probably caused by slipping of the fragments. The numbness is probably caused by nerve pressure. The treatment indicated is open operation, with living fascial suture.

The backward and upward displacement of the ulna entails a disruption of the inferior radio-ulnar joint. According to Wilson and Cochrane, if the displacement is marked a strain is exerted through the internal lateral ligament on the ulnar styloid and this is frequently fractured. In other cases it is the ligamentous attachment of the fibrocartilage that gives way instead or the cartilage may be torn across. With the continuation of the force and the rupture of the structures binding the lower ends of the radius and ulna together the distal radial fragment may be entirely separated from the head of the ulna which on account of the accompanying displacement of the hand backward and toward the radius appears to be dislocated forward in the wrist.

Anterior luxation of the head of the ulna usually incomplete may occur as part of the displacement complex in Colles's fracture. Posterior dislocation of the lower end of the ulna with or without accompanying fracture of the ulnar styloid may occur independently of fracture of the radius but is rarely encountered.

The injury apparently is caused by a severe twisting form of violence with hyperpronation of the forearm. The hand is held in the position of pronation rotational movements of the forearm are restricted with pain referred to the inferior radio-ulnar joint and the head of the ulna is prominent posteriorly.

Reduction is readily accomplished by strong traction on the hand with forward pressure on the head of the ulna followed by sharp supination of the forearm. The wrist should be fixed in the supinated position with the hand dorsiflexed on a molded

plaster cock-up splint. Immobilization should be maintained for three weeks in order to allow strong healing of the torn ligaments, without which a condition of chronic recurrent luxation is probable. The dislocation, even when reduced, is not easy to hold and a wrist strap should be worn for some time.

In a case of chronic recurrent luxation of six years' duration, Wilson and Cochrane found the attachments of the discus articularis and ulnar lateral ligament torn across, and they were repaired by the introduction of a fascial ligament passing from the ulnar portion of the disk to the posterior surface of the head of the ulna, where it was anchored in the bone. This resulted in a stable and painless wrist with good function.

MIGRAINE AND MENSTRUATION

To the Editor—A married woman aged 25 has been a sufferer from headaches and vomiting since her high school days. When the headaches appear, vomiting is obstinate and not even water can be held on the stomach. The spell lasts from six to forty-eight hours and may occur anywhere from one to five times a month. Her past medical history is irrelevant. The only abnormality noted is a history of amenorrhea for ten months following the birth of her only child (which was bottle fed). During the second and third trimester of her pregnancy and during the period of amenorrhea following the pregnancy the spells were absent. Physical examination reveals no definite pathologic condition. The patient wears glasses (the attacks come on whether she wears glasses or not). Pelvic examination reveals a superinvolution of the uterus. The gastro-intestinal system shows nothing abnormal and there are no foci of infection. (The tonsils and appendix have been removed and the teeth are in good condition. No evidence of sinusitis is present.) The blood pressure is 110 systolic 80 diastolic. Because of the history of amenorrhea and because although her periods are regular, they show a scanty flow ovarian injections were given between periods and corpus luteum right after the menses. No beneficial results were noted. Phenobarbital 1 grain (0.065 Gm.) a day has not produced any marked effect on the patient. I have finally narrowed down my diagnosis to this: (a) hypofunction of the ovary (b) migraine or allergic headache (cause unknown) (c) petit mal. Which do you think it is? Please omit name and address. MD Wisconsin

ANSWER—The most likely diagnosis in this case is migraine, which not infrequently occurs during the menstrual period. Women so afflicted characteristically advance the information that their headaches are absent during pregnancy and the period of nursing but return when the monthly flow of blood starts again. The headaches often disappear completely and permanently during the menopause. Further evidence of the correlation between migraine and the reproductive organs is the fact that these headaches often occur in women who have menstrual disturbances.

Since the only freedom from the attacks of headaches and vomiting this patient had was during an extended period of amenorrhea, it is logical to assume that an artificial menopause would bring about a cessation of these troublesome symptoms. However, since the patient is only 25 years old, this is out of the question at present. If the headaches and vomiting become absolutely intolerable and cause distressing symptoms, it might be advisable to produce a temporary amenorrhea by means of small doses of roentgen rays or radium, but even such a procedure should be resorted to as a measure of desperation. A much safer way to bring about a cessation of the menses and relief of the symptoms is for the patient to become pregnant again. If the past experience is repeated, she will have relief from the headaches and vomiting for about sixteen months.

SEDATIVES AND FLUIDS BEFORE OPERATION

To the Editor—Regarding the twenty-four hour preoperative period in laparotomies for hysterectomy or tumor what is thought by the best men regarding the routine use of sodium amytal and forced fluids containing alkalis by mouth? Is it not true that this fluid is probably excreted before operation is usually performed? And why the sodium amytal?

D B Rice MD Britton S D

ANSWER—No more reason exists for routine use of sedative before a hysterectomy than for any other major operation.

The reasons for a sedative are chiefly three: first, to permit the patient to get a good night's sleep; second, to avoid the preoperative nervous exhaustion period often unnecessarily long; and third, to permit the use of a smaller amount of anesthetic by its synergistic action. A fourth reason applies when procaine hydrochloride is used for anesthesia since drugs of the barbitol group are natural antagonists they prepare the patient against a toxic reaction from procaine.

It is good practice to give a small sedative dose of some of the barbitol group the night before an operation.

Many surgeons use the barbitals as preoperative preparation, giving one or more sedative doses in patients who tolerate it well. This is particularly indicated when local anesthesia is used. Some caution has been advised in liver damage and it is wise to limit their use in ether and chloroform anesthesia.

Fluids should be forced to the point of satisfying the tissue demand, and the same indication holds true for the preoperative use of alkalis. The excess will normally be excreted. Neither can be ordered for routine use but as a rule it is wise to increase the fluid intake the day before operation, since anxiety may actually limit the normal intake and nervousness may increase the normal excretion.

Since starvation, fever and toxemia tend to produce acidosis, alkalis may be indicated. On the other hand, in the presence of persistent vomiting an actual alkalosis may exist. Obtaining the amount, reaction and specific gravity of the urine is simple and usually a satisfactory method for determining the necessity for alkalis or forced fluids.

The preoperative addition of easily digested starches and sugars to the diet is commonly indicated, especially in operations producing a burden on the liver. Dextrose is frequently given subcutaneously before and after the operation, but tolerance toward it must be watched by repeated urine examination.

Sodium amytal has no demonstrable clinical merit over soluble barbitol preparations, which act quickly and may be given by hyperdermic injection.

The intravenous use of this group is contraindicated until tolerance has been established except in emergencies.

The use of the barbitol preparations by mouth is usually satisfactory.

Clinically phenobarbital and similar preparations in properly adjusted dosage are as satisfactory as amytal for their sedative action. Any of this group apparently may produce marked restlessness and a type of delirium in large doses.

It is probable that other sedatives may be equally satisfactory but many have more disadvantages than the barbitol group.

CAUSES OF HIGH PULSE PRESSURE

To the Editor—Please give me the causes of high pulse pressure. I have found this condition several times with apparently well functioning aortic valves.

L S MacMILLAN MD Rome NY

ANSWER—The pulse pressure is increased in essential hypertension in which the systolic pressure is generally increased more than the diastolic in arteriosclerosis and hence often in older people occasionally after severe hemorrhage in aortic regurgitation, and in myocardial disease associated with pulsus alternans, as a sign of improvement after an attack of cardiac failure, as a precursor of an attack of heart failure because of sudden increase in systolic pressure and with apparent or actual increase in auricular fibrillation. It is also increased normally after exercise, because of greater elevation of the systolic pressure than the diastolic.

DOSAGE OF COPPER WITH IRON

To the Editor—May copper citrate be used with Bland's pills (internal use)? If so kindly let me know the dosage.

EMILIE BRETTHAUER MD Suifu China

ANSWER—Yes. In doses of 0.01 Gm three times daily. There is no convincing evidence that the therapeutic effect is any better than that obtained for administration of iron alone, in the opinion of the Council on Pharmacy and Chemistry.

SUBCUTANEOUS NODULES AND BURSOPATHY

To the Editor—I have under my care a girl aged 11 who four months ago noticed swelling of the left knee with loss of weight and increasing weakness. Examination at that time revealed a bursitis of the left knee. Two months later swellings (enlarged bursae) appeared on the dorsum of both hands and on the right knee and both ankles. The weakness increased and she complained of slight pain and occasional stiffness of the joints especially the fingers. Examination showed the enlarged bursae of the joints mentioned but was entirely negative otherwise. Kindly advise probable diagnosis and treatment. Please omit name.

MD Minnesota

ANSWER—This case appears to belong to the group of synovial swellings, in which is included the condition referred to as Baker's cyst.

Pathologically some of these cases involve the tendon sheaths and rice bodies are occasionally found. The cause of this condition is usually infection. The important infections are those which cause rheumatoid arthritis, tuberculosis and syphilis. An article on Syphilitic Bursopathy by M J Morrissey and H S Reynolds appeared in *THE JOURNAL* April 22.

Considerable information may be obtained by aspiration and biopsy in order to determine the presence or absence of tuberculosis or syphilis. Guinea-pig inoculation and Wassermann and Kahn tests are indicated. The Pirquet test should be made human and bovine strains being used.

The treatment must be predicated on a diagnosis based on the recommendations made. The correspondent should refer to the works of MacCallum and of Dawson and Boots on subcutaneous nodules.

INDUSTRIAL HAZARD IN MANUFACTURE OF ASBESTOS BRAKE LININGS

To the Editor—In connection with the manufacture of asbestos brake linings it would seem that the material is pressed through a small gas oven measuring 2 feet by 2 feet which uses a mixture of coal tar 1 part alcohol 2 parts and bakelite 2 parts. Can you inform me as to whether or not the gas formed by these mixtures would be injurious on inhalation and whether or not the liquid itself would be dangerous on contact with the skin or to wounds?

A W LAZENBY MD Baltimore

ANSWER—Bakelite is a synthetic resin commonly dissolved in a mixture of benzene and ethyl alcohol. As a powder it is akin to hexamethylenamine (methenamine), which gives rise to the well known hen's dermatitis. Its irritant action is largely attributable to formaldehyde derivatives. Coal tar is a heterogeneous mixture of many high boiling point coal fractions. If benzene is used as a solvent or diluent for the bakelite the vapors present are a potential source of damage after intake through the lungs. The coal tar is only slightly evaporable but if evaporation occurs the vapors produced are conducive to inflammation of the respiratory tract.

The type of alcohol used is not specified but it is assumed to be ethyl. Its vapors in low concentrations may be ignored as a harmful agent.

The mixture as described is to be regarded as a source of dermatitis as its chief harmful property for the human body.

UNBALANCED DIETS IN TURKEY

To the Editor—I have been working for some years in Turkey where I have met a number of problems that baffle me. The diet of a large proportion of the patients that come to me consists chiefly of unleavened bread and some form of cracked wheat. This is pieced out among the better off with eggs, milk and fermented milk. For many of them vegetables and fruit are not available except during a few months in the summer. Most of these people have some sort of gastrointestinal complaint which I have considered to be in no small part due to the unbalanced diet. But another great difficulty that I have had was in dealing with the almost constant headache so often complained of. This too I have felt had a dietetic basis. The urine almost invariably is highly acid. Rendering the urine alkaline by medication has not been very successful. Moreover I have hesitated to give too large quantities of soda (for instance) lest the kidneys be injured. Should alkaline medication be useful and if so what form would be least harmful to the kidney? I need hardly say that these people are entirely unable to secure high priced concentrated vitamins to help out their diet.

WILLIAM L NUTE MD Talas Turkey

ANSWER—It seems difficult to try to reconstruct a diet along normal lines when the subjects cannot obtain the food constituents of a normal diet. Large quantities of soda or any other alkali should not be given indefinitely, but there is no reason why a moderate amount of any type of alkaline medication would be harmful.

DEPILATORIES AND SHAVING

To the Editor—I am troubled with a heavy and rapidly growing black beard. I usually shave around 7 o'clock in the morning and by 1 o'clock that afternoon it is hard to tell that I have ever shaved. Isn't there some form of depilatory that I could use on my face that would be non-irritating? Shaving twice a day is too irritating and I have not been able to find anything in the literature to help me in the form of a depilatory or beard retarder. Kindly omit name.

MD Georgia

ANSWER—There is no depilatory less irritating than shaving.

STRENGTH OF MERCURIC OXYCYANIDE SOLUTION FOR CONJUNCTIVITIS

To the Editor—Please state the strength of mercuric oxycyanide solution usually employed in the eye for conjunctivitis. Kindly omit name.

MD Illinois

ANSWER—1:5000 aqueous solution.

SULPHUR OINTMENT FOR SCABIES

To the Editor—Often I am in need of a scabicide for my charity patients. Please advise me of the cheapest preparation I can keep on hand to use with this class of patients. There are good scabicides on the market but they are too expensive for the average patient. Please omit name and address.

MD South Carolina

ANSWER—Sulphur ointment, U S P.

Maine July Report

Dr Adam P Leighton, Jr, secretary, Maine Board of Regis-
tration of Medicine, reports the written examination held at
Augusta, July 5-6, 1933. The examination covered 10 subjects
and included 100 questions. An average of 75 per cent was
required to pass. Fourteen candidates were examined, all of
whom passed. Nine physicians were licensed by reciprocity.
The following colleges were represented:

College	PASSED	Year	Number
Boston University School of Medicine	(1932)	(1933) 4	5

Book Notices

The Principles and Practice of Otolgoy By T W Watkyn Thomas
FRCS BCh Surgeon Central London Throat Nose and Ear Hospital
and A Lowndes Yates MC MD FRCS Honorary Assistant Sur-
geon Ear and Throat Department Prince of Wales Hospital Cloth
Temporary price \$6.25 Pp 555 with 199 Illustrations Baltimore
William Wood & Company 1933

Otolgoy will enjoy reading this book. The text embraces
the individual ideas of each of the authors. The section on
surgical anatomy of the ear is excellent. The illustrations are
largely different from those of the familiar treatises. They
are derived chiefly from the works of J E Frazer and from
Corning. There is an excellent chapter on the ear and balance,
and a good presentation of the subjects of hearing and the tests
of hearing. One could, if so minded, find things to complain
of. There are mistakes, such as the discussion of ligation of
the external jugular vein when the internal jugular vein is
meant. References to the literature follow each chapter. Many
of them are of abstracts published in English journals. Were
the references to the original article included, much time would
be saved for one pursuing information. The authors adopt the
method of testing hearing advocated by the Hearing Test
Committee of the Royal Society of Medicine. It is a unitary
system depending on the determination of the half intensity
period of the tuning forks used. In this country a similar
method has been advocated by Harvey Fletcher, using in the
calculation the constant of damping or decrement of each fork
as determined by the Bureau of Standards. All these methods
lead to increased accuracy in the testing of hearing defects,
but it seems highly desirable that some one method be adopted
and used universally by otolgoy. One can also question the
importance of local measures in the treatment of many types of
progressive deafness. However, these complaints are minor
when one considers the fresh point of view, the excellent and
unfamiliar illustrations and the large amount of valuable infor-
mation in a relatively compact work. Every English-speaking
otolgoy should possess this book, from the use of which he
will derive much pleasure and benefit.

Précis d'anatomie pathologique. Par Gustave Roussy, professeur à la
Faculté de médecine de Paris. Roger Leroux, professeur agrégé à la
Faculté de médecine de Paris et Charles Oberling, professeur agrégé à la
Faculté de médecine de Paris. In two volumes. Cloth. Price 175
francs per set. 1p 1314 with 586 Illustrations. Paris. Masson & Cie
1933.

In the past century, few authoritative textbooks or treatises
on pathologic anatomy have been published or edited by French
authors. The modern student of this subject has been com-
pelled to consult books written in German or English. The
present work therefore marks a noteworthy contribution to
French medical publications. Professor Roussy, who has been
head of the department of pathology in the University of Paris
since 1910 and his assistants have collaborated to produce one
of the best treatises on pathologic anatomy published in any
language. The two volumes are divided into eight sections.
The first two sections consider the fundamental lesions of
tissues of human beings and the circulatory disturbances. The
third and fourth sections deal with inflammation in general
and the inflammatory conditions in the special organs. The
last four sections are concerned with the general and special
details of new growths. The attempt to include all diseases
under the three headings of circulatory, inflammatory or neo-
plastic lesions encounters noteworthy difficulties. For example,
there is an almost total absence of consideration of develop-
mental anomalies or defects. Certain diseases, such as diabetes,
hypertension, vitamin disturbances and endocrine disturbances,

can hardly be treated adequately under any of these three headings. Of necessity there is considerable duplication, but the discussion under paragraph headings is clearly outlined and simply arranged.

The pathologic changes of thrombosis, inflammation, tuberculosis, tissues of the nervous system and carcinoma have been given particularly thorough review. Under "inflammation" the authors conclude their discussion (p 250) of its significance by this strictly scientific statement: "Inflammation presents itself, just as all other biologic phenomena, as a series of causes and effects. These actions and reactions without doubt are controlled by definite laws. It is these laws and not their philosophic interpretation which the biologist must recognize." As a rule their point of view is orthodox according to the modern teachings of pathologic anatomy, but a few exceptions may be noted. For example, functional hypertrophy of striated muscles is said to result from both division and increase in size of the fibers (p 488). In the discussion of the etiology of cirrhosis of the liver (p 808), alcohol is still given a primary place. Germinal centers are mentioned in lymph nodes, with no intimation of any other significance they may possess. Gastric mucus is believed to differ from intestinal mucus in that it does not stain with mucicarmine (p 575). In the discussion of colitis (p 938) there is no mention of the chronic ulcerative colitis caused by the diplococcus described by Bargen.

Few actual errors have been overlooked. The Greek word from which cirrhosis is derived is translated (p 802) as meaning "red" (roux) instead of its real meaning, "tawny yellow." The one reference to any medical work is to that of Laennec (p 806) and the year of publication is given as 1927. The principal defect is the lack of references to the literature. Various names of individuals are placed in parenthesis after certain facts or theories have been stated but there is no indication as to where their publications may be found. As would be expected, a large number of these are French writers, but German, English and American authors are also freely mentioned. The illustrations are really magnificent. Most of them are drawings, probably the best that any pathologic anatomy up to the present time has been able to produce. This is especially true of the splendidly accurate pictures of histologic lesions. They are abundant and extremely well chosen. The paper on which the book is printed is of good quality. Certainly these two volumes will take their place as worthy examples of the many medical classics produced by French authors and sponsored by French publishers.

The Biochemistry of Medicine. By A. T. Cameron, M.A., D.Sc., F.R.C. Professor of Biochemistry, Faculty of Medicine, University of Manitoba and C. R. Gilmour, M.D., F.R.C.P., Professor of Medicine and Clinical Medicine, University of Manitoba. Cloth. Temporary price \$5.50. Pp. 506 with 31 illustrations. Baltimore: William Wood & Company, 1933.

Here is a book that contains the medicine one would like to find in a textbook on physiologic chemistry and that contains, more particularly, just the amount of chemistry and no more, that one would like to find in a clinical textbook. The result is a pleasant, palatable and painless dose of chemical information for the progressive practitioner. The authors designed the book for the student of medicine receiving clinical instruction in the later years of his course, and for the physician who at school received little or no special instruction in the medical application of biochemistry. A large proportion of the current medical literature concerns itself with biochemical studies in the presence of disease, a comprehension of which is necessary for him who would keep abreast of modern scientific advances. The authors have kept their promise to express the chemical point of view as simply as possible. The book is in no sense a manual of practical clinical chemistry but a work that should enable the physician to coordinate biochemistry and clinical medicine for the solution of everyday problems of practice. In the first chapter, of twenty pages, is compressed an outline of human biochemistry. Other chapters are devoted to the normal and abnormal metabolism of carbohydrates, fats, proteins, water, organic compounds and ions. Still other chapters deal with respiration and respiratory disorders, the organic compounds of the blood, their function and the diseases associated with them, the endocrine secretions, vitamins and vitamin deficiency diseases, and lastly, notes on the biochemistry of a group of unrelated conditions, such as the toxemias of pregnancy, burns

and poisons, hypertension, tuberculosis and tumor. At the end of each chapter is a summary and an ample list of the pertinent references from recent literature. An improvement would be a handy outline of normal values for the various blood chemicals discussed. By relegating chemical formulas and details of laboratory technique to footnotes, the authors have returned for the work the character of being primarily a clinical textbook. The subject index bears out, even more than the table of contents, the book's right to be so classed. At least a third of its more than 500 indexed subjects are conditions of disease. Comprehensive, yet concise, the book's subtitle might almost be "the biochemistry of medicine made easy", at least it is made easy reading.

Diseases of Infancy and Childhood. By Leonard G. Parsons, M.D., F.R.C.I., Professor of Diseases of Children in the University of Birmingham and Seymour Barling, M.B., F.R.C.S., Professor of Surgery in the University of Birmingham, Birmingham, England. In two volumes. Cloth. Price \$25 per set. Pp. 1798 with illustrations. New York & London: Oxford University Press, 1933.

The scope of this work is rather ambitious, as it attempts to cover in two volumes the medical as well as the surgical aspects of the diseases of infancy and childhood. The authors have attempted to delete all tedious and wordy discussions, but in a book of this type it is difficult to maintain the proper balance of subjects. The editors have succeeded fairly well, considering their task. The contributors have been carefully selected and are well qualified to write on their respective subjects. A few Canadian and American pediatricians appear in the list of contributors. E. A. Park and Martha Eliot have written the chapter on rickets and Shipley covers the chapter on scurvy. The list of English contributors is impressive, and only a few of the better known men are omitted. The discussions for the most part are direct and concise. When disease processes are discussed, only such basic principles are included as will elucidate the subject under consideration. There is an attempt to cover the subject from a clinical standpoint as much as is possible. The preventive as well as the curative aspect of pediatrics is considered. Diagnosis and treatment is stressed throughout the text. Most of the subjects are adequately covered in a concise manner. The prospective purchaser might assume that because the work appears in two volumes the various subjects are covered in greater detail than in a single volume. The greater length of the work is undoubtedly due to the fact that the surgical disorders of infancy and childhood receive the same thorough but concise treatment as the medical conditions with which they are associated. This applies to surgery of the eye and ear as well as to orthopedic and general surgery. This work is notably free from antiquated data. The text shows the mark of careful editing and organization. The illustrations are clear but appear inadequate in some sections of the book. The reproductions of roentgenograms are particularly commendable and are the best that have appeared in a pediatric textbook. After each discussion a few well chosen references are given so that the reader may amplify the information if he so desires. The book will be of special value to clinicians as a concise and modern reference work on practically all the aspects of diseases of infancy and childhood. It is not a complete system on pediatrics but may serve a useful purpose as it is presented.

The Mode of Action of Drugs on Cells. By A. J. Clark, B.A., M.D., F.R.C.P., Professor of Materia Medica in the University of Edinburgh. Cloth. Price \$6.25. Pp. 298 with 62 illustrations. Baltimore: Williams & Wilkins Company, 1933.

In this volume Dr. Clark has collected and summarized the available data bearing on the fundamental problem of pharmacology, namely, the nature of the reaction between the drug molecule and the cell. This problem is not alone the most fundamental but is also still the most elusive and poorly understood in the whole field of drug research. The author's approach to an understanding is through the methods of quantitative pharmacology and statistical analyses of the results obtained. Some of the methods employed are: (1) micro-injection experiments, (2) quantitative estimates of drugs fixed on cell surfaces and entering the cells, (3) measurements of the rate of action of drugs, (4) measurements of the rate of wash-out of drugs, and (5) experiments showing the existence of active patches or receptors on the cell surface. The question of individual variation and its relation to drug action and idio-

synchasy is discussed. The skewing of normal characteristic curves relating to drug dosage and response is explained on this basis, it would thus be more correct in certain types of bioassay to express asymmetrical deviation as $+10-5$ instead of ± 5 . Various theories regarding the mode of action of hormones, vitamins and drugs are presented and analyzed in the light of existing data. It is shown that although certain drugs may be said to act by adsorption, or differential solubility, nevertheless the exact nature of the chemical reactions involved is far from being understood and that all the existing theories are inadequate in several respects. The influence of radiations, including heat, on living cells and the drug action thereon, is discussed in some detail. The material is presented in an interesting and readable manner and can be recommended as a brief survey of a detailed and difficult field. The extensive bibliography that follows each section makes the volume a valuable reference book, especially to the experimental pharmacologist.

Atlas der klinischen Elektrokardiographie mit Anleitungen zur Differentialdiagnose. Von Dr. Wilhelm Dressler, Assistent der Herzstation in Wien. Paper. Price 14 marks. Pp. 112 with 134 illustrations. Berlin: Urban & Schwarzenberg, 1933.

This collection of electrocardiograms is intended for the specialist already familiar with the elements of electrocardiography. It endeavors to show several curves of each of the various types of myocardial damage and arrhythmias. The electrocardiograms are placed on the page opposite their description thereby permitting the reader to interpret the electrocardiograms himself before reading the author's evaluation. No attempt is made to explain in detail the cause of the various changes seen or the mechanism of the various arrhythmias. The legends are complete and contain, when essential, a brief clinical report of the case. The author also outlines the manner in which the electrocardiographic diagnosis is arrived at. In making the electrocardiographic diagnosis, emphasis is placed on certain simple tests such as exercise and carotid sinus pressure. A differential diagnostic index is appended. The method of analyzing the arrhythmias is excellent and complete. Stress is laid, however, on the more unusual types of arrhythmias. The author still uses the classic terminology in bundle branch block and attempts to localize ventricular extrasystoles, procedures that are not generally followed today. The illustrations of electrocardiograms in coronary occlusion are not as typical as might have been used, and the author fails to make clear that in many of these curves the electrocardiographic diagnosis of coronary occlusion is made on the basis of the clinical history, which is not the usual procedure. Most authorities would consider one of the curves used to show right axis shift to be normal in configuration. But these are minor criticisms compared to the splendid handling of the majority of the electrocardiograms. This book can be highly recommended for the cardiologist wishing practice in interpreting the more unusual arrhythmias.

The Dynamics of Therapy in a Controlled Relationship. By Jessie Taft. Cloth. Price \$2.50. Pp. 296. New York: Macmillan Company, 1933.

For obscurity of diction this book might easily take a prize. To quote the author verbatim (p. 288): "Relationship therapy, then is nothing but an opportunity to experience more completely than is ordinarily possible the direction, depth, and ambivalence of the impulses which relate the self to the other, to enter reality, and to discover first-hand the possibility of their organization into an autonomous creative will." Or this: "The therapist who agrees to live for this limited time in the interest of his patient who gives up temporarily the projection of personal needs and impulses in order to allow the patient to work through his own unmolested provides an opportunity which is unique and irresistible in that it permits a realization of wholeness and security as part of a protecting supporting medium like nothing in human experience unless it be the intra-uterine existence. Many patients realize in this relationship for the first time a kind of cosmic ecstasy far beyond the sexual like that which the mystics describe as oneness with the harmonious flowing into reality. The body of the book is occupied by the verbatim record of two problem children: a seven year old boy and a seven year old girl whose problems she helps partially to solve by tactics that nurse

maids have discovered long ago letting the youngster believe it is having its own way and then checking it when it goes too far. That there is something in this kind of therapeutic relationship cannot be denied, but the author has neither discovered it nor clarified its dynamics, unless one considers "a sense of wholeness and security like that experienced in intra-uterine existence" an elucidation.

Operative Surgery. By Alexander Miles, M.D., LL.D., F.R.C.S., Consulting Surgeon, Royal Infirmary, Edinburgh, and D.P.D. Wille, M.D., F.R.C.S., Professor of Surgery, University of Edinburgh. Cloth. Price \$5.20. Pp. 590 with 321 illustrations. New York & London: Oxford University Press, 1933.

The authors have covered the subject in more than a satisfactory manner. Of course, operative surgery is so extensive and the techniques so varied that a good deal of condensation had to be done and the book cannot be called absolutely complete. Yet it fulfils the purpose for which it was written—to serve "as a guide to undergraduates in their class of operative surgery, and in the hospital, and to young graduates in their practice." The plan of the work is that usually followed in textbooks of this type. The first nine chapters deal with the surgical principles and operations pertaining to tissues in general, such as the blood vessels, lymph glands, peripheral nerves, bones and joints. The remaining twenty-five chapters discuss the technique of operations on the various organs of the body, including those of the face, mouth and air passages, with the exception of the female generative tract. An interesting and valuable feature of the volume is the short section on the surgical anatomy of the subject subsequently discussed which is placed at the beginning of almost every chapter. The work is concise and excellently written. The material is well selected, clearly illustrated and practical. Because of lack of space, the methods selected for description are those most favored by the authors and their collaborators, and of course represent present-day practice in the Edinburgh school.

La tuberculose du lobe azygos. Par B. Le Bourdellès, professeur agrégé du Val de Grâce et J. Jalel. Bibliothèque de phthisiologie sous la direction de Léon Bernard, professeur de clinique de la tuberculose à la Faculté de médecine de Paris. Paper. Price 40 francs. Pp. 159 with 70 illustrations. Paris: Masson & Cie, 1933.

This describes the supernumerary pulmonary lobes and the accompanying roentgenographic changes in health and disease. Accepting Aebys' definition, the authors hold that a lobe is that part of the lung extending to the pleura and depending on one or more primary bronchi and separated from other lobes by a pulmonary fissure. The azygos lobe is therefore not a true lobe like the cardiac and posterior middle lobes. The history of the development of knowledge of the azygos lobe, from its first description by Wrisberg in 1778 is fully given as well as its embryologic development, dependent on a higher entrance than normally of the azygos vein into the vena cava, which forces the pulmonary buds to grow around instead of pushing the vein to one side. The vein then comes to lie at the bottom of a fissure with the surfaces separated by two layers of visceral and two of parietal pleura ending at a point in the true interlobar fissure. The resulting azygos lobe may be large when the curved fissure is more horizontal or small when more nearly vertical. At a point near the apex the pleura is thickened in a falciform manner, which explains the triangular shadow there. The hairlike line concave to the left curves down toward the hilus and ends in a sharply defined comma-like shadow. The small twisted bronchus supplying the lobe favors the development of atelectasis. The lobe is stated to be present in 0.5 per cent of roentgenograms of the chest. Details variations and technique are thoroughly discussed. When a tuberculous process involves the right upper lobe, the azygos lobe may escape or it alone may be involved. Pleurisy with or without effusion may involve only the fissure. In artificial pneumothorax the fissure may be inflated with air. Excellent illustrations make these points clear. In a final chapter tuberculosis in other supernumerary lobes is discussed. The lobe of Rokitan'sky, a small isolated mass of fetal or atelectatic lung tissue completely isolated or attached to the left lower lobe occasionally situated extrathoracically is rare. The cardiac lobe, a portion of the lower lobe usually on the right is more common. Its fissure more clearly revealed by special technique extends as an extremely fine line from the hilus to the diaphragm. Tuberculosis may involve this lobe while

the remainder of the lower lobe escapes. The occurrence of bronchiectasis and telecystasis of this lobe is not stressed. One case of tuberculosis of the left azygos lobe is reported and attention called to the manner in which it differs from the right. The volume can be recommended to all students of roentgenography and tuberculosis.

Broadcasting Health. By J. Mace Adress, Ph.D. and I. H. Goldberger, M.D. Assistant Director of Health Education, New York City Public Schools. The Story Series in Health. Cloth. Price 80 cents. Pp. 401 with illustrations. Chicago: Ginn & Company, 1933.

The purpose of this volume is to provide pupils in the grades with an elementary survey of the field of nutrition and with special suggestions on training in wholesome attitudes on foods and food habits. There is, of course, far more to health than merely nutrition, but present-day methods have concentrated on nutrition in health teaching in the public schools. The volume begins with a simple statement concerning energy and its development. It covers all the current knowledge concerning water, air, minerals, the vitamins and then the specific food substances. It discusses the place of alcohol, tobacco, coffee, tea and condiments in the ordinary diet, much of the material being brought out by the conversational method. Most of the points of view are distinctly rational. The book is copiously illustrated with well selected photographs and includes also a glossary of definition and pronunciation of medical terms.

Die weiblichen Sexualhormone in ihren Beziehungen zum Genitalzyklus und zum Hypophysenvordrücken. Von Dr. C. Clauber, Privatdozent an der Universitäts-Frauenklinik Königsberg. 1. Pf. Paper. Price 22 marks. Pp. 191 with 103 illustrations. Berlin: Julius Springer, 1933.

The author divides his discussion of the field of the female sex hormones into several sections: (1) the histology and physiology of the genital cycles of the laboratory animals and man, (2) the follicular hormone, (3) the corpus luteum hormone, (4) the relationship of the follicular and luteal hormones, (5) the relationship of the ovarian hormones and hormone of the anterior lobe of the hypophysis, (6) and the hormonal diagnosis of pregnancy and chorion epitheloma. The book is profusely illustrated, mainly from the author's own experiments. Interesting ideas regarding the relationship of the sex hormones are advanced. The effects of hypersecretion of the follicular hormone and the hyposecretion of the luteal hormone are discussed. The author has spent much time investigating the corpus luteum hormone. This section of his book appears to be much better than the others. The book cannot be recommended to readers who wish to obtain an accurate picture of contributions of the various investigators of the female sex hormones. For example, though the discussion of the vaginal smear method of assay occupies six pages, Allen and Doisy, who introduced it, are not mentioned. Furthermore, the reference to that work is not given in the bibliography. Another error, equally glaring, is the failure to state that Doisy and his collaborators isolated the first crystalline follicular hormone. Many instances of this character could be given but it is hardly necessary.

A Text Book of Neuropathology. By Arthur W. Hall, M.D., Associate Professor of Neuropathology, Northwestern University Medical School, Chicago. Cloth. Price \$5. Pp. 335 with 260 illustrations. Philadelphia: Lea & Febiger, 1933.

This compact textbook discusses the pathology of the nervous system from a broad biologic standpoint and is to be commended for this, but a perusal of the book will convince one that the pathology of the nervous system is still largely histopathology. This phase of the subject is adequately and clearly presented in concise form suitable for students. The first chapter is valuable for one beginning the study of neuropathology. After four chapters on general neuropathology, the separate diseases are taken up briefly but adequately. The chapters on inflammations and intoxications are particularly to be commended. The chapter on tumors is adequate, in contrast to European books on the same subject. One should note that the appendix on staining methods is not meant to be a complete laboratory manual. The literary style is decidedly Germanic. It is a pity that neuropathology cannot be cleared of German words and phrases that are readily translated into English. This book can be heartily recommended as an authoritative introduction to its subject.

Les conjonctivites folliculaires. Rapport présenté au 46^e congrès de la Société Française d'Ophthalmologie, le 27 juin 1933. Par V. Morax. Société Française d'Ophthalmologie. Paper. 1 p. 142 with 22 illustrations. Paris: Masson & Cie, 1933.

The author defines follicular conjunctivitis as an inflammation of the ocular mucous membrane, characterized by hyperemia, lacrimation, secretion, and the formation of follicles in the transitional folds of the conjunctiva. That gave him a fairly wide latitude, on which he proceeded to elaborate with the thoroughness that has always been synonymous with the name of Morax. Some twenty odd pages are given over to the historical phase of the subject, followed by a nearly similar number of pages of clinical description. Particular emphasis is laid on the condition known as swimmers' conjunctivitis and the investigations of the etiologic factors of that disease. This, of course, leads into an elaborate discussion of the Prowaczek bodies and their relationship to inclusion blepharitis and to trachoma. Then follow the description and differential diagnosis of trachoma and the various other forms of follicular conjunctivitis. Treatment is dismissed with a disdainful gesture in one and a half pages. The conclusion is that there are four main types of follicular conjunctivitis: trachoma, swimmers' conjunctivitis, acute conjunctivitis with follicles, and chronic follicular conjunctivitis. An elaborate and complete bibliographic index completes this interesting brochure. The colored illustrations are somewhat better than fair, but the black and white ones are rather indifferent. The booklet represents an enormous amount of work, both clinical and literary, and is well worth the attention of the clinical ophthalmologist.

Le disque intervertébral. Physiologie, pathologie, indications thérapeutiques. Par C. Maurie, 1^{er} adjoint de Pasteur, Valléry-Bidot. Paper. Price 30 francs. Pp. 195 with 45 illustrations. Paris: Masson & Cie, 1933.

In this monograph the author presents the anatomy, embryology, physiology, pathology, radiologic aspects and therapeutic indications concerning the subject of intervertebral disks. The works of Luschka, Hueck, Schmorl and Junghans, Calve and Galland and Beadle and others are reviewed. The illustrations are generally good, especially the pathologic sections. This is an important subject and has recently experienced a well deserved awakening of interest.

Internal Derangements of the Knee Joint. Their Pathology and Treatment by Modern Methods. By A. G. Tinbrell Fisher, M.C., M.B., Ch.B., Surgeon (With Charge of Out Patients), Seamen's (Dreadnought) Hospital, Greenwich. Second edition. Cloth. Price \$3.50. Pp. 204 with 190 illustrations. New York: Macmillan Company, 1933.

This monograph is based on a careful clinical and experimental study of the internal derangements of the knee joint. Special emphasis is placed on the application of therapeutic measures founded on accurate knowledge of structure, function and disease. The value of manipulation and its place in the treatment particularly of injuries and adhesions are well discussed. The section on internal derangements due to damaged or diseased semilunar cartilages takes up a large part of the book and gives a comprehensive yet brief description. There is a short history of the subject of internal derangements and a brief discussion of the surgical anatomy, physiology and mode of production of the derangements of the knee joint. The pathology, symptoms, differential diagnosis and treatment are clearly described. Other varieties of internal derangement are outlined more as a summary of the author's experience and studies rather than in a detailed form. An appendix of notes by Sir Robert Jones is of especial interest because it is probably his last. The author is to be credited with a classic summary of his experience and for including only the essentials.

The International Medical Annual. A Year Book of Treatment and Practitioner's Index 1933. Fifty First Year. Edited by Carey F. Coombs, M.D., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc. Cloth. Price \$6. Pp. 72 with 159 illustrations. Baltimore: William Wood & Company, 1933.

This medical annual is now in its fifty-first year. It begins with a review of a year's work in therapy. It provides incidentally an obituary notice of Dr. Carey F. Coombs, who died this year and who was for fourteen years editor of this publication. The volume is contributed to by a great number of writers selected by the editors, all of them British and all of

them well known for work in the fields to which they contribute. It has a fine index and is fully illustrated with many plates, some of them in colors, most of them borrowed from current periodicals. The book constitutes a good reference work, particularly for those who want the latest word on any medical subject.

Inorganic Colloid Chemistry Volume I The Colloidal Elements By Harry Boyer Weiser Professor of Chemistry at The Rice Institute Cloth Price \$4.50 Pp 389 with 54 illustrations New York John Wiley & Sons Inc London Chapman & Hall Ltd 1933

This gives a good critical survey of the colloidal behavior of elements and their inorganic compounds with particular reference to their role in the development of colloid science. It is concerned primarily with the methods of formation, properties and application of the elements in the colloid state, which includes their uses or their tentative uses in medicine. The elements included are gold, silver, copper, mercury, alkalis and alkaline earths, lead and miscellaneous colloidal metals including antimony, the iron and platinum families and the nonmetallic elements carbon, sulphur, selenium, tellurium and iodine. The essentials of this part of colloid chemistry are presented in a clear, concise, accurate style, with numerous references to the literature. The therapeutic discussions, however, give one the impression of a chemist, with the will to believe, peering at medicine through the keyhole. The facts are that most of the reported benefits of colloidal therapy do not withstand reasonable criticism. The book is instructive and stimulating and it may be studied with profit by medical men without especial training in mathematics or chemistry.

Medicolegal

Malpractice Injury Attributed to Physician's Absence During Childbirth—The plaintiff employed the defendant to attend her in childbirth. When delivery seemed imminent he directed her to go to a hospital. He examined her there, about 10:30 o'clock, p. m., and concluded that the baby would not be delivered before the following day. After instructing the nurses and attendants to telephone to him at once if a change occurred, he went home. Shortly after midnight he received a call, but although he arrived at the hospital within about ten minutes the birth was already about completed. He assisted only in the last stages. The defendant attended to plaintiff while she was in the hospital and discharged her at the usual time. The plaintiff instituted her suit when, according to her testimony, she developed uterine trouble which she attributed to the defendant's failure to attend her during the entire time of her labor. The trial court directed a verdict in favor of the defendant, and the plaintiff appealed to the Court of Appeals of the District of Columbia. The evidence, said the Court of Appeals, discloses no testimony to show that the absence of the physician was the proximate cause of the plaintiff's trouble. There is testimony that her condition may have been caused by the childbirth, but there is no evidence to show that if the defendant had been present and exercised reasonable professional skill the result would or could have been different. The Court of Appeals affirmed the judgment of the court below.—*Bonner v Conklin (District of Columbia)*, 62 F (2d) 875

Insurance "Totally and Permanently Disabled" Construed—The defendant insurance company issued a policy by which it agreed that if the plaintiff should become disabled by bodily injury or disease so as to be permanently, wholly and continuously prevented from engaging in any occupation whatever for remuneration it would during the continuance of such disability waive the payment of the premium on the policy and pay the insured a stated monthly benefit. About June 27, 1929 the plaintiff became totally disabled. On October 19, the same year he presented to the defendant insurer proof of total and permanent disability dating back to June 30. When this proof was presented neither the plaintiff nor his physician knew how long disability would continue but on or about June 1, 1931 disability ceased and the plaintiff resumed the practice of his profession. The insurer refused to pay the benefits

promised by the policy, and the plaintiff brought suit, Oct. 1, 1931. It was conceded that during twenty-three months the plaintiff was totally disabled. The defendant contended, however, that the disability was not permanent, because it had ceased before the suit was commenced, and that therefore the plaintiff was not entitled to the agreed benefits.

The word "permanent," as used in this insurance contract, said the Supreme Court of Minnesota, is to be construed according to its nature and in relation to the subject matter of the contract. The insurer agreed to waive the payment of premiums and to make monthly payments "during the continuance of such disability," which does not indicate that the insurer meant that the disability must continue until the insured died. The policy authorized the insurer to demand of the insured from time to time new proof of continuing disability, and this, the court believed, implied that the insurer contemplated that disability might terminate. As was said by the Supreme Court of Georgia in *Penn Mutual Life Ins Co v Milton*, 160 Ga 168, 127 S E 140, in construing an insurance policy similar to this one,

This language clearly indicates that the insurer meant that the total disability on proof of which it would grant the benefits named was not one which might last during the entire life of the insured but one which might end prior to his death.

We are of the opinion, said the Supreme Court of Minnesota, that the authorities support the conclusion that in insurance parlance, in such a policy as that now before us the words "totally and permanently disabled" contemplate a disability which reasonably satisfies a fair and impartial mind that the insured is then totally disabled and may reasonably be expected to continue in that condition for at least an indefinite period of time. If a person insured under such a policy has been totally disabled for sixty days and proves by competent evidence the nature and character of his disability and that it will probably continue, or may continue, for life, or that it may reasonably be expected to continue indefinitely, he is entitled to recover instalment payments as one who is totally and permanently disabled. Subsequent recovery, even before trial, does not destroy the insured's cause of action, though it does terminate the accrual of subsequent instalment payments under the policy.

The order of the court below, directing a verdict in favor of the defendant insurer, was reversed.—*Maze v Equitable Life Ins Co of Iowa (Minn)*, 246 N W 737

Workmen's Compensation Acts Compensability of Pneumonia—The industrial commission of Wisconsin awarded Hatfield an employee of the Yellow Cab Company, compensation under the workmen's compensation act, because it found that he had contracted pneumonia out of and incidental to his employment. The Yellow Cab Company appealed to the Supreme Court of Wisconsin. The expert medical testimony given before the industrial commission, said the Supreme Court, warranted the commission in finding that, although pneumonia germs are prevalent in the throats and noses of many normal persons, pneumonia does not result unless the germs invade the lungs and multiply there. This occurs from a lowering of resistance, which may be due to exposure, alcoholism and reduced vitality following an operation. The commission was warranted in finding also that the claimant's exposure was the logical cause of the lowering of his resistance, which caused the development of pneumonia. Clearly, the claimant's pneumonia was incidental and fairly traceable to his employment, he would not have been equally exposed to it apart from his employment. Likewise the chances of the growth of the pneumonia germs and of the resulting pneumonia were substantially increased by the services which he was obliged to render. The fact that such a hazard is incidental also to all similar outdoor activities is no reason for denying the claimant the benefits of the workmen's compensation act. The judgment of the lower court affirming the award, was therefore affirmed.—*Yellow Cab Co v Industrial Commission (Wis)*, 246 N W 689

Compensation of Physicians License a Prerequisite to Recovery of Compensation—Where the law requires a person who practices a profession, such as medicine or pharmacy, to obtain a license, one who practices without having obtained such a license cannot recover compensation for services so rendered.—*Horsely v Baker (Iowa)* 246 N W 653

SECOND CONFERENCE ON RHEUMATIC DISEASES

Held under Sponsorship of the American Committee for the Control of
Rheumatism Milwaukee June 12 1933

(Concluded from page 1184)

Nutritional Aspects of Chronic Arthritis

DR A A FLETCHER, Toronto There is little evidence of metabolic disease among arthritic patients. Almost all chemical studies give normal results. A few women with osteo arthritis seem to show an inherent tendency to become heavy, particularly after the menopause. Control of their weight is helpful, whether the disease is inflammatory or degenerative. A lowered metabolic rate occasionally contributes to increase in weight. In atrophic arthritis maintenance of weight is difficult, sometimes impossible. This tendency to loss of weight may be constitutional or may be associated with chronic infection or gastro-intestinal dysfunction. At times, a diet high in calories, and insulin seem useful. There is little evidence that disturbance in metabolism of uric acid occurs in arthritis independent of gout. It has been asserted that some patients with arthritis are sensitive to acid, but there is no chemical support for this statement, and it is doubtful whether the so called alkaline diets are based on any true metabolic principles. In the belief that the process in rheumatoid arthritis is an exudative one, restriction of salt and water has been advised by Straus, Berkhardt and Gerson in Germany, and by others. An allergic reaction to some food may be present in the occasional case.

There is experimental evidence that faulty nutrition, particularly during prenatal life and adolescence may lead to states of subnormal health conducive to disease in later life. In cases of atrophic arthritis, the frequently asthenic build, loss of weight, nervous instability, and tendency to premature aging might be considered nutritional phenomena. The motor disturbances of the gastro intestinal tract, atony, ptosis, and lack of haustral markings in the colon as seen in chronic arthritis may be due to deficiency of vitamin B and excess of carbohydrate. At times diets high in vitamin and low in carbohydrate will reestablish normal tonus of the bowel. Atony of the colon can be produced experimentally in rats with a fair degree of certainty with diets high in carbohydrate and low in vitamin B. The colon also becomes longer and the ileocecal valve markedly incompetent. The longer this condition persists, the more difficult it is to restore its tonus. In time such deficiency goes on to atrophy and metaplastic change in the mucous membrane.

The person who is disposed to, or who is suffering from rheumatoid arthritis must live a protected existence. Just as he is liable to fatigue, vulnerable to strain susceptible to infection and poorly adaptable to environment change so he does badly on diets of poor quality and does well on protective diets. At times the gastro-intestinal tract has a more immediate causal relationship to the disease such as in the arthritis of bacillary dysentery and of ulcerative colitis. Other conditions occur in the gastro-intestinal tract the significance of which

is not so well established disturbance in motility, the presence of nonspecific inflammatory conditions in the bowel, aberrations of intestinal flora and the presence of organisms productive not only of fermentation and putrefaction but of more invasive ones, such as hemolytic streptococci. There has been, in this country, much resistance to accepting the belief that such processes may play any part in the cause of arthritis. These intestinal disorders are seen among patients who do not have arthritis. Other factors must be necessary for the arthritis. Probably one of the essential factors is injury to the mucous membrane from an impaired nutritional state.

There is no agreement as to what measures are applicable for the treatment of deranged bacterial flora. Colonic irrigations, laxatives, rough diets, vaccines or the implantation of bacteria are extensively used, at times with relief. Foul stools indicative of proteolysis in the bowel, may be grounds for short periods of restriction of protein. More often the history suggests a fermentative process, such as production of gas, and relief is obtained by restriction of carbohydrate or cellulose. Short periods of dietetic restriction, and the use of rough diets or of smooth diets, all serve to cater to disturbed gastro intestinal function, but in their use it must be remembered that the optimal state of the patient's nutritional health should not be impaired by such measures. Clinical and experimental evidence suggests that this may be maintained and that for weeks or months material improvement in the general health of arthritic patients occurs with a diet high in all vitamins, low in carbohydrates, moderate although adequate in protein of good biologic value and moderate in total calories.

DISCUSSION

DR T PRESTON WHITE, Charlotte, N C Our patients seem to do much better on a diet low in carbohydrates and high in vitamins, but close attention must be paid to intestinal elimination for poor elimination is evidently a large factor in keeping up arthritis. We attempt to restore the patient's weight to normal. At times we disregard all diets, feeling that the patient must first be restored to normal health.

DR R GARFIELD SNIDER, New York Our experiments with feeding of vitamin B have not produced the clinical results or roentgenologic appearance noted by Dr Fletcher. My associates and I have used wheat germ in the forms advocated by him and have encouraged patients to take them in as large quantities as possible for periods varying from two to eight weeks. In about fifty cases the results were disappointing clinically and roentgenologically. Definite clinical improvement, either in the form of improved intestinal elimination or decreased pain in the joints, did not occur either during or following the period of feeding of vitamin B. Roentgenologically the changes in the colon described by Dr Fletcher could not be demonstrated. The colons of these patients did not reveal any distinctive changes in size, configuration, tonicity, haustration or position. Generally the bowel looked the same before and after the period of feeding of vitamin B. In a small number of cases the colon appeared to be of wider lumen, more atonic, of greater redundancy, and to be more ptotic than before the experiment was begun. I believe that these changes are extrinsic, transitory and not necessarily indicative of intestinal injury. Is it not possible that Dr Fletcher's interpretation of intestinal improvement following feeding of vitamin B is due to changes in the appearance of the bowel produced by variations of roentgenologic technique rather than to intrinsic changes in the colon? In some of these cases we give colonic irrigations twice a week. Colonic irrigations given over a period of years do not produce any deleterious changes in the colon demonstrable roentgenologically.

DR W J KERR, San Francisco Drs Rinehart and Mettler recently attempted to produce chronic scurvy in guinea pigs by giving foods deficient in vitamin C. They found infiltrations of cells in the valves of the heart and in many tissues of the body presumably similar to Aschoff bodies. This work should be repeated and if confirmed may alter ideas concerning the etiology of rheumatism. Rheumatic diseases recur, are affected by climate and may be related to inability to obtain proper vitamins in winter months.

DR M H DAWSON, New York Has Dr Fletcher had any experience with diets high in carbohydrate in rheumatoid

arthritis? We have recently employed such a dietary regimen in a number of cases, with rather marked improvement.

DR A A FLITCHER, Toronto Many factors influence the tonus and shape of the colon. Observations regarding the influence of diet should be made under careful control. Dr Snvder had his patients under a prolonged course of treatment with enemas, and his observations are thus open to criticism. I have recently observed a case in which vitamin B, given intramuscularly, brought about rapid improvement in tonus, and there seems to be no doubt that at times, clinically, variations in the vitamin B content of the diet, and the balance of the diet, are the most important factors in changing the shape of the colon. Sometimes an arthritic patient may improve with almost any abrupt change in diet. Diets high in carbohydrate especially if given with injections of insulin to a patient who is much underweight, will result in increased strength and weight and in this way will increase resistance to infection. Such a diet should not be allowed to become inadequate in any other food factor.

Contusion of Cartilage as an Etiologic Factor in Chronic Arthritis

DR J ALBERT KEY, St Louis Contusions of the articular cartilage may heal without symptoms or may lead to the development of chronic arthritis in the injured joint. When the latter occurs, the degenerating cartilage should be excised. I have recently done this in two cases. The first case was that of a young man who struck his right knee on a beam. Severe pain and swelling resulted, which subsided under treatment, but the joint often became stiff and, on overexertion, sore and swollen. There was no sensation of catching or locking in the joint. The knee was slightly thickened and tender to pressure just lateral to the patellar ligament. On flexion, maximal tenderness appeared to be proximal to the external semilunar cartilage. The roentgenogram was negative. A diagnosis was made of traumatic arthritis of the left knee, with contusion of the articular cartilage of the external condyle of the femur. On exploration the diagnosis was confirmed and the injured necrotic cartilage, about 2 cm in diameter, was removed. The clinical result was satisfactory. Similar cases have been reported by Budinger, Ludloff, Ahausen and Lawen. I have been able to produce arthritis by resecting a rectangle of cartilage in rabbits, but not in cats, and only occasionally in dogs. Apparently, in patients, the defect in cartilage created by surgical excision heals with a fibrous or cartilaginous base and does not tend to produce progressive arthritis.

DISCUSSION

DR JAMES A DICKSON, Cleveland In examining a knee after injury it is likely that the possibility of injury to articular cartilage will be ignored. If examination discloses that the ligaments are intact and that the semilunar cartilage is not injured it is likely that the use of bandages, protection and physical therapy will be continued indefinitely. Dr Key has demonstrated the fallacy of such an attitude and the importance of consideration of the possible production of osteochondritis dissecans. In cases in which symptoms persist, and it is possible to demonstrate roentgenologically the typical picture of osteochondritis dissecans, I do not hesitate to remove the loose cartilage. Results have been uniformly gratifying. Roentgenologic observations must not be depended on entirely to determine whether exploration is indicated. Exploration should be made more often in cases of posttraumatic disturbance of joints with persistent symptoms. No harm is done thereby, and undoubtedly a great deal of time often is saved and a more satisfactory result obtained. A thorough examination of the condyles should be made whenever the semilunar cartilage of the knee is being explored. Osteochondritis dissecans without roentgenologic signs is undoubtedly more frequently present than is usually believed and if this condition should be kept in mind in studying posttraumatic symptoms referable to joints undoubtedly many more cases would be revealed than are diagnosed at present. When the diagnosis is made, the patients respond excellently to treatment.

DR R K GHORALEY, Rochester, Minn. The amount of trauma that may occur to cartilage from daily activities is not realized. Certainly strain of the back and strain of other joints will produce changes concerning which physicians have no con-

ception unless the joints are taken out and examined, which, of course, is not often done. Fibrillation has been found in many joints. In chronic flatfoot the same fibrillation of the cartilage is seen.

DR J A KEY, St Louis I was not referring to osteochondritis dissecans because I do remove the loose bodies from such joints when there is no marked arthritis. Two patients may suffer almost exactly the same injury, but one will develop chronic, progressive arthritis and the other will have no trouble with the joint. There must be differences in reaction to injury that determine the course of events after trauma.

The Treatment of Chronic Arthritis

DR W J KERR, San Francisco The common denominator in most methods of treatment that are reputed to be of value is the exhibition of improved circulation in the affected joint, whether this is brought about by local or by general measures. Methods that improve circulation are useful in both proliferative and degenerative arthritis.

The local measures of value are of several types: (1) the use of counterirritant agents and methods, such as liniments, salicylates, blisters, cupping, cautery, ultraviolet rays, constrictive hyperemia and other ways of producing local hyperemia from stasis, (2) wet or dry heat as applied by water, mud, baths, infra-red radiation, diathermy and other methods, (3) cold in the form of cold baths, showers, douches and exposure to cold or bracing air, such as is employed in the open air treatment of tuberculosis of a joint, (4) sympathectomy or ramiectomy to relieve the vasoconstrictor tonus of an extremity, and (5) radiotherapy of sympathetic ganglions.

The general measures used to improve the circulation of a joint are: (1) general exercise, (2) increased intake of water, which may affect the volume of blood in circulation, (3) the use of vitamin C, which may tend to restore injured capillaries of those whose diet has been deficient in this respect, (4) administration of thyroid extract, which may increase the peripheral flow of blood, (5) use of foreign protein in the form of vaccines, peptones, serums and other foreign substances, which may produce so-called protein shock which results in temporary or more prolonged improvement in peripheral circulation, (6) general use of heat by changing the patient's residence to a warmer climate, by applying radiant heat in cabinets, by use of hot baths, by applications of short waves (pyrotherapy), (7) anesthesia, (8) removal of foci of infection, and (9) other operations which may give temporary benefit to the patient by the exhibition of protein shock.

DISCUSSION

DR M F LAUTMAN, Hot Springs, Ark. Heat is often indiscriminately applied, and much of the disrepute that it has met is due to the fact that a physician tells his patient to go home and take baths as hot as he can stand. The patient goes home and sits in a tub of hot water until he becomes weak and exhausted. Consequently, he is not benefited. Hydrotherapy properly applied with the understanding that there is an optimal temperature which every patient can tolerate to his advantage, is one of the safest and best methods that can be used to improve both articular and general circulation.

DR L T SWAIN, Boston At what time in the stage of arthritis is exercise of the joint indicated? My experience is that if the joint is immobilized for a time the disease is quieted more rapidly and there is much less injury. Exercise in the early stages should be avoided until the disease is quiescent. In several cases the only joints which did not undergo ankylosis were those which were protected and rested with casts. Proper attention to the joint in the early stages may prevent a great deal of injury from unnecessary trauma and strain.

DR W H KERR, San Francisco It seems to me that fixing a joint in a cast for a long period is about the worst thing that could be done. It is important to change the position of the joint from time to time.

Analgesia Accompanying Hepatitis and Jaundice in Cases of Chronic Arthritis

DR P S HENCH, Rochester, Minn. In the course of the last four years observations have been made on the effect of intercurrent intrahepatic jaundice on the chronic pain experi-

enced by sixteen patients with chronic arthritis, fibrositis and sciatica. In two of the cases the intrahepatic jaundice apparently was not related to drugs, in fourteen cases it was considered the result of toxic hepatitis caused by cinchophen. Coincident generally with the onset of jaundice, fourteen of the sixteen patients received partial, usually complete, relief of pain for variable periods, moreover, in five of the six cases in which the joints were swollen, reduction of the swelling, sometimes complete, also was noted.

Five of the sixteen patients experienced complete analgesia, which was prolonged for from two weeks to eight months in one instance for seven years, after disappearance of the jaundice. Four patients noted complete disappearance of pain with the onset of fatal hepatitis and jaundice caused by cinchophen, the analgesia persisted until death. In one case, complete relief of pain was noted only for the duration of icterus, in another case, pain disappeared completely at first, returning slightly during the latter part of the period of jaundice. Two patients had marked, although not complete, relief of pain during jaundice, and even thereafter, for two weeks and five months, respectively. No amelioration of pain was experienced by two patients with slight jaundice, and one other noted some relief, which later was lost, even in the presence of definite icterus. In an additional case, of chronic infectious arthritis and hepatitis caused by cinchophen but without jaundice, no relief of pain was experienced.

Analgesia associated with hepatitis and jaundice has not heretofore received detailed comment so far as I am aware. The mechanism whereby analgesia is produced is not known. The duration and degree of relief of pain were roughly proportional to the duration and intensity of the jaundice, as shown by the concentration of serum bilirubin, in at least one case, relief of pain preceded the appearance of visible icterus. The effect is probably not specific and may or may not be the result of a depressant effect of some component of jaundice on the nervous system, or to a sedative action on inflamed tissues. The therapeutic implications are obvious. It would be gratifying were one able to repeat nature's miracle, to provide at will a similar beneficence by the use of some nontoxic component of jaundice effective in available concentration. To explore the possibilities of such treatment, a group of patients is being treated with various substances suggested by this study.

DISCUSSION

DR NATHAN SIDEL, Boston. It is interesting to speculate on the possibilities for future treatment of arthritis in view of these interesting observations that are encountered when jaundice occurs in arthritis. I recently saw a man about 39 years of age who had severe psoriasis followed by severe infectious arthritis so-called psoriatic arthritis. With the onset of an attack of infectious hepatitis or catarrhal jaundice there was tremendous improvement in his arthritis. For several years he had been taking about six tablets of acetylsalicylic acid daily because of pain, but with the onset of jaundice no acetylsalicylic acid was necessary, because all pain of the joints had disappeared. Throughout the fairly intense jaundice, which lasted about five weeks, the patient felt remarkably well and had no pain or stiffness in the joints. With complete disappearance of jaundice some pain and swelling of the joints recurred, but not as much as before the jaundice. Although he has now been free from jaundice for at least four weeks, acetylsalicylic acid has not been necessary, and his pains have been only slight. Within the last two weeks I have given this man two injections of decholin intravenously, but he has not noted any improvement as yet. Another patient, a woman, aged 50, who had infectious arthritis for several years, also experienced improvement in her arthritis with the onset of jaundice. In 1931 a physician prescribed capsules of "oxyiodide." After a few days the patient began to feel better, but ten days later intense jaundice developed lasted five weeks, and was not of the obstructive type. The pains of arthritis disappeared completely with the onset of the jaundice and have remained absent for more than two years. About four weeks ago the patient again began to have some pains in certain joints. She has not taken any medicine fearing to take even acetylsalicylic acid. Dr George Minot of Boston told me that in cases of coexistent pernicious anemia and arthritis, when anemia was marked and the skin tinged yellow, the arthritis was likely to be much

better, with improvement in color and blood count the arthritis sometimes became distinctly worse, demanding treatment. The two cases mentioned one of infectious hepatitis and the other of toxic hepatitis, the observation of Dr Minot, and the experiences of Dr Hench, make one speculate as to whether a clue to the future treatment of arthritis may have been discovered and whether, by giving patients the essential constituent of jaundice which causes relief of pain, relief may be brought about therapeutically.

DR M. H. DAWSON, New York. Did any change in the peripheral circulation occur in these cases?

DR S. S. KIEFFER, Boston. During the last two years I have seen two patients who, during a definite attack of hepatitis, had arthritis for the first time. With subsidence of hepatitis, the arthritis disappeared. I also observed a patient with hemolytic jaundice who during the course of the disease, had attacks of gout, with marked elevation of the value for uric acid in the blood. The attacks occurred before as well as following splenectomy.

DR P. S. HENCH, Rochester, Minn. Dr Russell Haden of Cleveland told me yesterday of a patient with severe chronic atrophic arthritis who last year received complete relief from pain with the onset of jaundice, apparently from neosarsphenamine given empirically. Complete analgesia has persisted to date and in effect the patient is entirely normal. Studies on peripheral circulation were made only in my most recent case. The cutaneous temperatures were normal.

The General Principles of Treatment in Chronic Arthritis

DR G. R. MINOT, Boston. The general principles of treatment of chronic arthritis are to improve all functions of the body, to modify or remove the basic causes, to prevent or control organic changes, and to make adjustments that will lessen the burden of the handicapped organism. The two main types of chronic arthritis are generalized disorders with manifestations in joints and thus the treatment must be directed first toward the patient as a whole and only secondarily toward the joints. The patient must appreciate that he requires a long period of training and, like the physician, must not doubt that wisely conducted treatment leads eventually to success in a large proportion of cases. Rest, habitual relaxation, and tranquility of mind are of the utmost importance in the treatment of arthritis as they are in tuberculosis. Relief from strain of all types must be secured. There would be fewer crippled arthritic patients if the milder and ambulatory cases were treated at once with a program of rest. Exercise of the correct kind and amount and at suitable times, is also important. It influences favorably the retarded capillary circulation and all bodily functions.

There is of course, no standard diet for arthritis. The quantity of the food should not be excessive, and the nutritive quality especially of the protein, should be superior. Removal or alleviation of infection is of distinct importance, but foci of infection must not be eliminated on haphazard advice. To eradicate infectious foci and to do nothing else is comparable to bailing a boat and leaving the hole open. Infection probably plays a much more important part in atrophic than in hypertrophic arthritis. Foci of infection should be removed as early in the course of the disease as possible, for it is then that best results from their eradication are obtained. The physician must not pride himself that he, or even the patient is responsible for all improvements because nature tends to heal the disease.

Intensive treatment, begun early, offers the patient a much better prognosis than if it is delayed until the disease has existed a few years. Enough time for adequate treatment is fundamental. Arthritis touches many fields of medicine. One man must be the patient's chief and take full charge of him and his case. To teach the art of courageous living is often the chief prescription for the patient with chronic arthritis.

DISCUSSION

DR R. B. OSGOOD, Boston. One cannot treat the patient's body only and not consider his mind. A patient must be treated as a whole. The disease cannot be cured by one procedure certainly not by vaccine therapy alone and probably not alone by the brilliant and fascinating things Dr Hench has suggested.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Prolan A in Teratoma Testis—Ferguson reports a series of 117 consecutive cases of teratoma testis, in which he studied the quantitative excretion of prolane A. He describes the Zondek technic for the quantitative estimation of prolane A in the urine. The patient with teratoma testis will excrete from 50 to 50,000 mouse units of prolane A per liter of urine depending on the embryonal character of the tumor the extent of the disease and the status as regards treatment. Irradiation of the primary tumor and its metastases causes a decrease in the excretion of prolane A in the urine. Local recurrence or metastasis is accompanied by an increase in the excretion of prolane A in the urine frequently before clinical detection of the lesion is possible. Serial observations at frequent intervals while the patient is under active treatment by irradiation give important prognostic information. Observations at necropsy reveal the important relation between the hormone of the anterior lobe of the pituitary and epithelial hyperplasia in the genital organs of the male particularly the prostate and seminal vesicles.

Pupillary Test for Pregnancy—Bercovitz studied the pupillary reactions of pregnant women, nonpregnant women and men. One drop of a 10 per cent solution of sodium citrate is mixed with 5 or 6 drops of the patient's blood and instilled into one eye. The other eye is used for control observation and comparison. The test requires about two minutes and the reaction usually lasts for about five minutes. Of the 138 women who were not pregnant, none showed a positive pupillary reaction. Sixteen men gave negative reactions. There were no false positive reactions. In 183 patients the diagnosis of pregnancy was confirmed by subsequent events. Of these, 155, or 84.7 per cent showed positive pupillary reactions. In one there was a positive pupillary reaction twelve days after the onset of the last menstrual period. Forty one postpartum cases were observed. Thirty-four gave negative pupillary reactions. One patient who had a positive reaction before delivery gave a negative reaction fifteen minutes after the delivery of twins and the placenta. Phenol, 0.2 per cent in physiologic solution of sodium chloride will prevent or abolish a pupillary reaction of pregnancy. Neutralized female sex hormone, isolated from the urine of pregnant women failed to cause a pupillary reaction when instilled into the conjunctival sac of fourteen pregnant women. All these women reacted positively to their own blood.

Treatment of Uterine Bleeding with Snake Venom—Peck and Goldberger treated twelve patients with snake venom for functional uterine bleeding. The period of time in which bleeding was controlled varied from five days to two and three weeks. In most of the patients it required about six injections given over two to three weeks before any definite effect was noted. With the control of the uterine bleeding there was a rapid improvement of the secondary anemia usually present. The venom of *Ancistrodon piscivorus* was used in 1:3,000 dilution with sterile physiologic solution of sodium chloride containing 1:10,000 merthiolate. It was given intradermally. The initial injection was 0.2 cc and subsequent injections were 0.4 cc, given two times a week. The therapy was continued for from three to six months. Treatment should be given for at least three months, even in the presence of marked clinical improvement. For the first five or six injections, care should be taken that the injection sites are separated from one another at least 10 cm. The left and right arm and the right and left thigh can be used. If hypersensitivity occurs, it is advisable to reduce the concentration to 1:10,000 and to continue the injections until a dose of 0.4 cc of 1:3,000 is used. By this means, desensitization without any untoward reactions was obtained in practically all cases. The injections should be planned as follows: 0.1 cc of 1:10,000, 0.4 cc. of 1:10,000, 0.2 cc. of 1:6,000, 0.4 cc of 1:6,000, 0.1 cc of 1:3,000, and 0.4 cc of 1:3,000.

Friedman Pregnancy Test—The present modification of the Friedman pregnancy test, as adopted by Vesell in 533 cases, showed 100 per cent accuracy. A positive result has been obtained after the death of a fetus for a period of from four to six weeks in gestations of six months duration or

more The procedure differs from the original Friedman test in that 7 cc instead of 5 cc of urine is injected Necropsy is performed in forty-eight hours instead of twenty-four Female rabbits of any size, weighing at least 1,600 Gm, instead of virgin rabbits may be used In cases of early amenorrhea, the same rabbit is re injected with 7 cc of the same urine, twenty-four hours after the first injection The urine is kept in the icebox between injections Necropsy is performed forty-eight hours after the initial injection

Diagnosis of Bone and Joint Tuberculosis—According to Pomeranz, the criteria utilized in the roentgen diagnosis of tuberculosis are subject to diversified exceptions which make accurate interpretation of this disease extremely difficult The changes in the bones and joints are dependent on the severity and duration of the process as well as the specific locality involved The presence of a sinus and infection introduces factors whose roles in the process are extremely difficult to evaluate The intelligent appraisal of characteristic changes and the modifications produced by extraneous circumstances determine the successful diagnosis of the disease The usual roentgen changes of joint tuberculosis are synovitis and periarticular swelling bone atrophy or sclerosis bone production and destruction in the epiphysis and metaphysis, narrowing of the joint space sequestration and the presence of cold abscesses or sinuses 1 Synovitis periarticular swelling and bone atrophy are common to all arthritides and are only of corroborative

value in the diagnosis of tuberculous arthritis Bone atrophy is usually marked, but its intensity is modified by numerous imponderable factors which complicate diagnosis 2 Sclerosis and bone production occur in tuberculosis even in the absence of a mixed infection When sinuses exist, bone production may be absent Diaphyseal tuberculosis in long tubular bones is rare and, roentgenologically, the diagnosis is impossible 3 Wedge or cone shaped lesions are usually tuberculous 4 'Kissing' sequestrums are common in tuberculosis 5 Narrowing of a joint space which occurs late in an infection, despite associated destructive changes, is strongly presumptive of the existence of tuberculosis 6 Complications, such as kyphosis subluxation and sinus formation, occur in tuberculosis as well as in other arthritides 7 Roentgenologically, the presence of a cold abscess specifically identifies the process as tuberculous

Primary Chondroma of Lung—Benninghoven and Pearce point out that the majority of primary chondromas of the lung are located near the pleural surface The neoplasm is usually round or oval varies in size and is always encapsulated Two characteristics, the nodular, lobulated structure and the tendency to undergo calcification or osseous transformation, are important from a roentgenologic standpoint Microscopically the most prominent element is cartilage, both the hyaline and the fibrous type are frequently encountered In the roentgenogram a primary pulmonary chondroma should present (1) an abnormal mass of great relative density surrounded by a normal air-containing lung, (2) a sharply defined lobulated border and (3) within it scattered, irregular areas of even greater density representing calcium or bone In the differential diagnosis the sharply defined periphery of the chondroma surrounded by normally aerated lung is easily distinguished from an encapsulated chronic inflammation (old abscess or tuberculous lesion with calcification) Cellular infiltration in the immediate lung parenchyma usually accompanies an inflammatory condition It is absent in the neighborhood of the chondroma Solitary echinococcus cysts of the lung occur more often than primary pulmonary chondroma The roentgenographic appearance is similar, but the border of the shadow of the echinococcus cyst is smoother and there may be slight cellular infiltration in the surrounding lung parenchyma The cystic mass is usually of homogeneous density The history of previous infestation with *Taenia echinococcus*, potential exposure to the parasite, and the complement fixation test are of value in making the differentiation The tumor is essentially nonmalignant except when its location produces a mechanical obstruction It can be successfully removed, if necessary, when favorably situated and without fear of recurrence The neoplasm is sufficiently characteristic, roentgenographically to permit identification without microscopic study

Addisin in Diseases of Blood—Morris and his associates state that the hematopoietic hormone (addisin) is a normal constituent of the gastric secretion of man, dogs, swine and cattle It is probably distributed widely in the animal kingdom

dom Addison may be recovered in a form suitable for intramuscular injection by concentration in vacuo, by dialysis and by conversion to an ethyl ester. A preparation for intravenous use has not yet been obtained. A single large dose of addisin may be sufficient to induce a remission in pernicious anemia and is more effective than repeated small doses. There is evidence to suggest that the cause of erythremia may be a hyperscretion of addisin or a hypersusceptibility to stimulation by it on the part of the bone marrow. The results of treatment of acholuric jaundice with addisin are sufficiently encouraging to warrant further trial. The possibility of establishing normal maturation of the red cells is suggested. In a patient with agranulocytic anemia, the leukocytic reaction and clinical improvement have been remarkably prompt. In this disease it is possible that addisin may be curative. Theoretical considerations indicate the possibility that addisin may play a significant part in other blood dyscrasias.

Changes in Heart Shadow in Toxic Goiter—Menard and Hurxthal made roentgenograms before and after treatment in 115 cases of toxic goiter. Comparisons of the films were made by measurement and by superimposition. Definite reduction in size was observed after congestive heart failure was relieved and after auricular fibrillation had ceased, and in a few cases without these complications. The authors conclude that superimposition of seven-foot roentgenograms of the heart is the most satisfactory method of judging changes in the size and shape of the heart. Very little change takes place in the heart shadow in uncomplicated cases of toxic goiter with normal rhythm following removal of thyroid toxicity by subtotal thyroidectomy. Cardiac dilatation as shown by roentgenograms takes place most frequently in congestive heart failure with or without auricular fibrillation. Occasionally, in cases of toxic goiter of sufficient duration, uncomplicated by other cardiovascular disease, certain changes in the heart shadow may be found which have been described as characteristic of hyperthyroidism.

Retropharyngeal Abscess of Otic Origin—Faier states that a retropharyngeal abscess if left to itself may result in any of the following complications: particularly when overlooked oftentimes being undiagnosed and discovered only at necropsy. (1) Spontaneous rupture into the esophagus may occur. (2) rupture into the air passages may occur, with production of pneumonia, lung abscess or sudden asphyxia, (3)

pus may burrow laterally and appear externally, anterior or posterior to the sternocleidomastoid muscle. (4) pus may pass downward behind the esophagus and enter the posterior mediastinum, (5) the process may spread by way of the blood and lymph channels to cause septicemia, pyemia or meningitis, (6) the abscess may cause erosion of the large vessels of the neck, such as the internal carotid artery or internal jugular vein, (7) respiration may be interfered with by pressure on the larynx with production of edema of the glottis, (8) jugular thrombosis may result, (9) cardiac failure may occur by pressure on the vagus and sympathetic nerves, and (10) pus may extend into the axilla along the subclavian vessels and brachial plexus. Retropharyngeal abscess may be caused by suppuration in the retropharyngeal lymph nodes, caries of the cervical vertebrae and burrowing of pus from other regions by direct extension. Burrowing of pus may be the result of infection following injury to the posterior wall of the pharynx from an injury or a foreign body, otitic infection, suppuration of the parotid gland and lymph nodes, dental infection and tonsillar and posttonsillectomy infections. The author reports nine cases in which suppurative otitis media was an important etiologic factor in the formation of the retropharyngeal abscess.

Blue Mantles in Otosclerosis—Weber has histologically examined fifty-one human temporal bones showing otosclerosis but no signs of Paget's disease. In all fifty-one labyrinthine capsules the bone surrounding the otosclerotic focus showed processes of transformation. This transformation of bone made its appearance in the form of perivascular mantles and in 28 per cent of the cases examined in the form of so-called blue mantles. With the silver stain (after Bielschowsky-Maresch) and with the aid of the polarized light, especially with the new "two-picture method" of the author (i. e., one photomicrograph of the hematoxylin-eosin stained section and another photomicrograph of the same object in polarized light), it was found that the blue mantles consisted of a primitive, mainly plexus-like pathologic bone tissue, newly formed after previous lacunar absorption of the surrounding bone from the vessel space. The remaining 72 per cent showed red mantles and mixed mantles. The mixed mantles consisted partially of plexus-like bone and partially of lamellar bone. The red mantles consisted only of lamellar bone. All these perivascular areas followed previous absorption. The author concludes that otosclerosis cannot be regarded generally as a purely primary focal disease but must be regarded as a disease at least of the whole labyrinthine capsule. He discusses the significance of this fundamental result for the problem of otosclerosis. The investigations of the author lead him to believe that in every case of otosclerosis the general skeletal system shows pathologic changes.

Galvanic Current in Atrophic Rhinitis—During a period of six years Stovin used the galvanic current in atrophic rhinitis. It has proved the most satisfactory. With this he depends solely on the stimulating effect on the mucous membranes and nerve endings and not on any chemical effect of some medicinal agent such as zinc sulphate being driven into the membrane by the current. He finds that the stimulation of the mucous membrane tends to restore partially its normal physiologic functions and that the stimulation of the olfactory nerve endings improves the sense of smell. He employs the following method. The nose is thoroughly cleansed by wet

suction, warm physiologic solution of sodium chloride being used. The fluid is run into one nostril, the head being lowered, while the patient says "K-K-K," and the return flow is sucked from the other nostril into a suction bottle. The nasal tips are alternated several times during the procedure so that the nose will be thoroughly cleansed of all mucus and crusts. The nostrils are then packed with successive layers of absorbent cotton strips which have been dipped in physiologic solution of sodium chloride. These should completely fill the nose from the floor to the roof, including the olfactory area. The cotton strips should be long enough to extend half an inch out of the nostrils. The active pole is attached to the protruding cotton and the inactive pole is held in the patient's hand or attached to his arm. The current is turned on and the rheostat moved up slowly until the patient experiences a salty taste in the mouth. The millimeter reading is usually between 5 and 10. The current is applied for fifteen minutes and the packs are removed. An oil, such as balsam of Peru in castor oil or Mandl's solution, is applied to the mucous membrane. These treatments are given three times a week at first and later, as improvement is noted, at longer intervals. Improvement occurs when the membranes become redder, moist and thicker. The postnasal discharge lessens and the sense of smell is markedly improved.

Injuries of Semilunar Cartilage—Wright states that the treatment of an injured lateral ligament with displaced or injured cartilage or of a severe injury of the lateral ligament alone is: 1 Reduction, accomplished by nearly full flexion, internal rotation of the tibia, and extension, preferably under an anesthetic. 2 Injection of from 5 to 10 minims (0.3 to 0.6 cc) of tincture of iodine at the point of greatest tenderness, and deep enough to reach the tibial border, to create an aseptic inflammatory reaction sufficient to aid the cartilage to adhere. 3 Fixation in extended position by a light plaster cast with only stockinet or a single bandage lining, and a piece of silence cloth over the knee and the prominence of the head of the fibula. 4 A rest of one or two days, after which function should be permitted by walking, i. e., weight bearing. 5 Muscle redevelopment. 6 Prevention of mechanical stress by elevation of the heel of the shoe on the inner border for internal cartilages. In acute primary injuries the swelling may be so tense and the pain so severe as to make the early fixation in plaster inadvisable in which case extension should be preserved by a posterior splint and rest, and, if the pain is acute, aspiration is advisable and will give great relief.

Osteitis Fibrosa—Leggett reports a case in which the areas of osteitis fibrosa were associated with benign giant-cell tumors. In the single lesion of this condition good results

have been obtained by thorough curettage and phenolization of the interior of the tumor. This may or may not be followed by the inlay of a bone transplant, which course will be determined by the function of the part. Zinc chloride has also given good results. Packing the cavity with gauze may lead to infection and should not be done, as fatal hemorrhage may occur when the packing is removed. The limb should be immobilized to prevent pathologic fracture. To prevent recurrence, radium or high voltage roentgen therapy is recommended. Irradiation results only in a 20 per cent recurrence. A certain amount of danger is involved in employing radiation too soon after operation, as a local breaking down of the skin may follow with subsequent infection. During the early months the tumor may increase in size under irradiation but this increase is soon followed by a shrinking of the growth and formation of a new dense bone. In multiple cases, irradiation appears to be the only possible line of attack.

Treatment of Headache with Chondroitin Sulphuric Acid—While studying the action of chondroitin sulphuric acid in peptic ulcer, Crandall and Roberts observed a striking effect on the headaches of which a number of the patients complained. The headaches in these cases were not due to previous alkali therapy. In two of the patients, the headache was definitely migrainous in character. Therefore they administered chondroitin sulphuric acid to forty-two patients with idiopathic headache. More than 50 per cent have been markedly benefited, and another 30 per cent appear to be partially relieved. The cases are classified as migraine, migranoid or simple headache. The authors discuss the criteria for these classifications. The proportion of improvement in the three groups is similar. The period of treatment varied from two to twelve months. As a rule continued administration is necessary to maintain improvement. The optimal dosage, administered orally, has appeared to be 3 Gm a day, only rarely has benefit resulted from larger doses. The response appears to be equally satisfactory whether the substance is given three times a day in divided doses or the whole amount once daily.

Treatment of Endocervicitis—Soter believes that the treatment of endocervicitis by thermocauterization or electrocoagulation is the method of choice. Surgery should not be done until after one of these methods has been tried. Prophylaxis after parturition and repair of cervical tears will help to reduce materially these infections and prevent more serious trouble. The treatment and cure of endocervicitis often mean the prevention of cancer. Reduced physical resistance predisposes to these infections. Indiscriminate douching and careless vaginal examination often introduce them. Complications following thermocauterization and electrocoagulation are possible and due caution should be used in patients before the menopause.

Complement Fixation Test in Amebiasis—Craig bases his observations on the results of the complement fixation test on the blood serum of 1,000 persons suffering from definite symptoms of amebiasis such as amebic 'carrier' cases having no symptoms of the infection, patients in the wards of a general hospital suffering from other disease conditions than amebiasis, and patients sent to him for examination or seen by him in consultation. The technique employed by him has not differed from that described in 1929. A human hemolytic system is used; the serums to be tested are inactivated by heating at 56 C in the water bath for half an hour, and the antigen employed is an alcoholic extract of 48 hour old cultures of *Endamoeba histolytica* grown on the Boeck-Drbohlav medium. The test was not considered positive unless a three or four plus reaction was obtained on a four plus scale. The specific complement fixing bodies disappear from the blood serum following antamebic treatment and the disappearance of *Endamoeba histolytica* from the feces. In relapsing cases of amebiasis the complement fixation test which has been negative during the interval of apparent freedom from *Endamoeba histolytica*, again becomes positive in rare instances even before the parasite is again demonstrable in the feces. The time of disappearance of the positive complement fixation reaction after treatment resulting in the disappearance of *Endamoeba histolytica* from the feces has varied between three and twenty-eight days. In 86.6 per cent of the cases the reaction disappeared within fourteen days after the cessation of antamebic treatment and in 96.6 per cent within twenty-one days. Persons infested with other species of amebae or with the intestinal flagellates do not give a positive complement fixation with this test unless *Endamoeba histolytica* is also present. The complement fixation

reaction gives the strongest positive results in symptomless "carriers" or in those presenting mild symptoms of infection with *Endamoeba histolytica*. The test has proved of value in the diagnosis of cases of amebic abscess of the liver unaccompanied by intestinal symptoms, in the diagnosis of apparently healthy "carriers" of *Endamoeba histolytica* and of persons presenting atypical or mild symptoms of infection, and in the control of antiamebic treatment.

Rheumatoid Arthritis—Stainsby and Nicholls treated 103 patients by removing diseased tonsils. Sixty showed subsequent improvement of their arthritic condition. Twenty had no other form of therapy, while eighty-three were also given streptococcus vaccine. No higher rate of improvement was noted in patients having vaccine and tonsillectomy combined than in those having tonsillectomy alone. The results in the tonsillectomy group were best in young patients and those having mild arthritis. Of thirty-five patients who had abscessed teeth removed, twenty-four showed improvement. Thirty of the thirty-five also received streptococcus vaccine therapy. The authors attribute the high percentage of improvement in these patients to the removal of abscessed teeth. Of 194 patients treated with vaccine therapy alone, sixty-nine showed improvement. The authors' results with vaccine therapy were extremely disappointing, as the low percentage of improvement may well represent the natural tendency of some patients to improve regardless of treatment.

Primary Sarcoma of Heart—Morris reports an instance of primary sarcoma of the heart in a case which unfortunately furnished little clinical history. The tumor was a small round cell sarcoma originating in the right auricle, which, because of the apparent normal health of the deceased during the fifteen years of his life, must have been insidious in onset but after that became a rapidly growing fatal neoplasm.

New Blood Plasma Chloride Method—In their blood plasma chloride method, Cavett and Holdridge prepared a Folin-Wu filtrate of the blood or plasma (1 cc of blood or plasma, 7 cc of water, 1 cc of two-thirds normal sulphuric acid and 1 cc of 10 per cent sodium tungstate thoroughly shaken together and filtered). They pipetted 5 cc of the filtrate into a large test tube and added 0.2 cc (three drops) of a fresh 5 per cent solution of sodium nitroprusside. Mercuric nitrate (1 cc is equivalent to 1 mg of sodium chloride) is added from a microburet until a permanent turbidity is produced on the addition of one drop (Titration value in cc $\times \lambda \times 200 =$ mg of sodium chloride per hundred cubic centimeters of plasma). The titration corrections (λ) which Kolthoff and Bak determined for varying concentrations of corrosive mercuric chloride in water are slightly low for the Folin-Wu filtrate, therefore the titration is made directly on the Folin-Wu filtrate and the end point is easier to observe than that obtained with the methods now in use.

Paralyzed Diaphragm—Meade subjected six dogs to unilateral transpleural phrenic neurectomies. In four of them, paralysis and atrophy of the corresponding halves of the diaphragm were still present when the dogs were killed ten months later. In two regeneration of the phrenic nerves occurred with a complete restoration of normal function and of normal gross appearance of the diaphragm in one and an uncertain restoration in the other. Studies of the tensile strength of the

two halves of the diaphragm were made which showed consistently and significantly higher figures for the paralyzed half. Whether or not the difference is a true one cannot be definitely concluded at this time. It can, however, be definitely stated that a decrease in tensile strength of the diaphragm does not result from phrenic neurectomy.

Pyelitis and Ureteritis Cystica—Kindall reports a case of pyelitis cystica and ureteritis cystica diagnosed by urography and confirmed at operation and, so far as he can determine by a study of the literature, the first case conclusively diagnosed. Cystoscopy was of no diagnostic value, since there was no cystitis cystica present. Combined intravenous (by means of a new urographic contrast agent) and bilateral, retrograde pyeloureterograms were made throughout the study. The dilated ureters were due to obstruction of the lumen of the ureters by the cysts, mechanically causing back pressure or interfering with the functional peristalsis of the ureter. The author states that large ureteral catheters passed to the kidney pelvis and left in place for several days mechanically rupture many cysts and that the injection of silver nitrate solution at the time of removal, by its astringent action destroys other traumatized cysts.

Treatment of Prostatitis by Injection—Grant has applied mercurochrome directly to the interior of the infected gland in prostatitis. To do this, he first fills the bladder with water and then while keeping a guiding finger in the rectum he introduces a 6 inch, 22 gage needle through the perineum of the patient in the lithotomy position. The needle is kept in the middle line and, by close adherence to the rectal wall, the possibility of injuring the bulb is avoided. The needle can be felt to pass through the prostatic capsule by the definite increase in resistance and, once it is through this point, it can be directed to the portions of the gland at will. The hub of the needle is then attached to a Loktite syringe and a 1 per cent solution of freshly made mercurochrome is injected into the gland. The amount of fluid to be injected is gaged by the pressure felt. As the needle is withdrawn, a light flow of the fluid is maintained to sterilize the tract it makes in the perineum. From 10 to 20 cc of mercurochrome is injected at various points throughout the gland, accompanied by gentle massage of the prostate to disseminate the drug. The treatment in the first 100 cases was confined to chronic prostatitis without any demonstrable disturbance in the vesicles. Since then the author has injected all types of infected glands many times doing a vasopuncture and injecting mercurochrome through the vasa. In all his cases of epididymitis in which he deemed surgery advisable he injected the prostate at the time of doing the epididymotomy. He has used this treatment in more than 400 cases and so far has not had a single untoward result. Not all cases are improved, but the proportion of cures both from a clinical and a laboratory standpoint has been high. The author concludes that the injection of mercurochrome promotes rapid disappearance of pus and organisms from the prostate and diminishes the duration of the disease.

- Diagnosis of Mild Smallpox and Scarlet Fever. C. Armstrong. Washington, D. C.—p. 1257.

"Alcoholic" Polyneuritis—Minot and his associates treated fifty-seven patients with undoubted "alcoholic" polyneuritis, who had gastric analyses performed or adequate dietary histories taken and usually both, by a diet rich in complete proteins, minerals and vitamins. This daily diet included from 150 to 250 Gm of beef liver pulp, 200 Gm of orange juice, 100 Gm of muscle meat, 500 cc of milk and large helpings of fresh vegetables, fruits and butter. Concentrated carbohydrate food was given sparingly. Daily about 60 cc of cod liver oil and 12 Gm of autolyzed yeast or extractives were given each patient and iron when indicated. The authors believe that under this regimen recovery has been observed more uniformly and with greater rapidity than previously. However, evaluation of therapeutic results in the absence of a 'yardstick' to measure such results is notoriously difficult, and in a condition of as chronic a nature as polyneuritis, in which regeneration of nerve tissue occurs only slowly at best, it is hazardous to interpret what causes benefit. Since patients were admitted in all stages of the disease and in all states of health, it was impossible to compare intelligently and statistically the results of treatment with special diets and those obtained in other ways. Furthermore, dietary treatment has been employed as a routine in recent years so that comparisons could be made only with cases treated by other individuals and there appear to be no published data for proper statistical comparison while hospital records do not furnish satisfactory information for such a purpose. Alcohol itself may act not only as a poison to the nervous system but also by diminishing the effectiveness of vitamins. Cowgill has shown that the amount of vitamin B required by the organism is in some measure proportional to the total metabolism. The consumption of much alcohol may lead to an abnormal increase of daily total metabolism since a quart of whisky furnishes at least 2800 calories, so that an unusual demand for vitamin B might develop. The concept that dietary deficiency, especially the lack of vitamin B₁₂, plays an important part in the production of "alcoholic" polyneuritis is favored by the grossly deficient diets taken by the patients for a long time, and the similarity of the lesions and symptoms to those of beriberi. The seasonal variation, the precipitating influence of infection and the frequent occurrence of achlorhydria are similar to what occurs in certain known deficiency disorders. Pellagra and other dietary deficient states may occur in persons with alcoholic polyneuritis. If a good diet rich in protein and vitamins causes more satisfactory improvement than any other form of therapy, it only strengthens the fact that a state of deficiency causes polyneuritis in chronic alcoholism.

Pyelitis of Pregnancy Treated by Nephrostomy—Phaneuf and Graves report a case of severe pyelitis complicating pregnancy. All the usual medical and cystoscopic measures having failed to give relief, a right nephrostomy was resorted to with satisfactory results. Two other complications developed in the form of otitis media with mastoiditis and perirectal abscess. The patient was in such a weakened condition that the complications were treated conservatively. Two small blood transfusions were administered. Labor occurred without serious mishaps at a time when the patient's general health had improved. The child gained normally. The nephrostomy sinus closed immediately following delivery. The mother subsequent to her discharge from the hospital, had a mastoid operation performed and made a good recovery.

 Diagnosis and Treatment of Some Laryngeal Conditions R F Ridpath Philadelphia—p 678

Diseases of Ductless Glands—Rowntree states that hormone treatment in the form of substitution therapy, if properly applied, as a rule is effective in its immediate results, but these are of short duration requiring frequent administration of the hormone concerned. Administration of hormones has been almost always unsatisfactory and completely ineffectual if given by mouth, except in the case of desiccated thyroid in hypothyroidism. The following hormones have proved their effectiveness clinically and can be advocated therapeutically: insulin in diabetes mellitus, desiccated thyroid or thyroxine in myxedema and early in cretinism, ampoules of pitressin in diabetes insipidus, parathyroid extract in parathyroid tetany and eschatin, the cortical hormone of the suprarenals, in Addison's disease. Eschatin has already established its value in a limited clinical trial so far as immediate results are concerned. Hormone therapy is assuming a new and important part in relation to surgery in diminishing the operative risk and mortality and by contributing to the postoperative recovery in patients afflicted with diseases of the ductless glands. The study of patients with tumors of the endocrine glands reveals, as a rule, the clinical manifestations of excessive amounts of the hormone concerned. The surgical removal of such tumors results, as a rule in the temporary appearance of a paradoxical deficiency demanding the temporary administration of the hormone concerned. Tumors of the endocrine glands emphasize the importance of the constitutional effects of tumors and call for the more comprehensive study of the problem involved, in relation to other types of tumors. The recent and important advances made in the fundamental fields have tremendously enhanced the opportunity for true service to the sick. This concerns practically all the major fields of practice, especially medicine, pediatrics, gynecology, urology and surgery.

Phenol in Treatment of Tetanus—Bryan gives the three plans of treatment for tetanus (1) the specific serum plan (2) the magnesium sulphate plan and (3) the phenol plan. Some physicians combine two of these plans as a routine method. The author treated six patients with phenol, all of whom recovered. Several of these had antitetanic serum before the phenol treatment was begun and during the treatment. They were placed on phenol intravenously in 1 per cent aqueous solution. The doses were usually given twice daily. Two of these cases were mild one was rather severe three were severe. The maximum dose often far exceeds 15 Gm of phenol every twenty four hours.

 *Plasma Phosphatase in Rickets and Other Disorders of Growth Jean Smith—p 215
 Normal Hemoglobin Level During the First Year of Life Revised Figures Helen M M Mackay—p 221

Plasma Phosphatase in Rickets—Smith found the average plasma phosphatase of ten normal breast-fed healthy infants to be 0.248 unit, with a range of from 0.2 to 0.3 unit. The plasma phosphatase of a group of healthy infants fed on artificial foods, but with additional fat-soluble vitamins A and D and with water-soluble C, ranged from 0.2 to 0.36 unit, with a mean value of 0.3 unit, i e, approximately the same as that of healthy breast-fed infants. The plasma phosphatase is increased in active rickets. In a group of sixteen cases of radiologic rickets, the figures varied from 0.41 unit to 1.29 units, with an average of 0.772 unit. In a series of infants fed on artificial foods but not receiving extra fat-soluble vitamins, the average plasma phosphatase was 0.52 unit, with a range of from 0.4 to 0.702 unit. As long as these vitamins were withheld the plasma phosphatase increased, and when these were added the values fell to within normal limits. Conditions characterized by cessation of growth, such as cretinism, scurvy and achondroplasia, are associated with an abnormally low plasma phosphatase. All infants fed on artificial foods should be given additional fat-soluble vitamins within a few weeks of birth.

Immunologic Studies with Virus of Psittacosis—The investigations of Bedson bring out that the serums of persons convalescent from psittacosis possess no demonstrable neutralizing power but will fix complement in the presence of a psittacosis antigen. Similarly the serums of hyperimmunized guinea pigs contain considerable antibody demonstrable by complement fixation or agglutination but only a low neutralizing power. The author discusses the value of the complement fixation reaction in the diagnosis of psittacosis. Virus that has been rendered inactive by means of formaldehyde can evoke a considerable degree of immunity in the mouse. Virus treated with solution of formaldehyde in wood alcohol and water can be steamed for twenty minutes without much loss of its immunizing power whereas steaming alone has a deleterious action.

Rehalational Anesthesia—During the past two years, Halton has evolved a technic of rehalational anesthesia, which takes its place between perhalation with the ordinary mask and rebreathing into a bag. The apparatus consists of a small cylinder of oxygen and a J size carbon dioxide sparklet which are strapped together and tubes from which are brought to a Y-piece, whence a further tube leads the gases to the mask. A 4 ounce ether drop bottle with a dropper delivering an even drop in any position, and a modified Ogston mask. A section of motor car inner tube slipped over the frame takes the place of the towel or lint which Ogston suggested, a short length of metal tube is clipped to one of the uprights, and the gases are by this means, led to the depths of the mask. Ether, chloroform and ether mixture or ethyl chloride can be employed. With anesthesia fully established, the carbon dioxide is turned off and the patient is evolving and rebreathing his own carbon dioxide from the mask chamber. Respirations are deep and full, and, when there is a slight tendency to cyanosis, sufficient oxygen is turned on to counteract this. It will be found that ether can be dropped almost as sparingly as chloroform. No freezing of the gauze will take place, provided the drops are not directed constantly to one portion of the mask, and, unless a deep level of anesthesia is required, when the whole of the gauze is moist the drops should be directed to the sides of the mask. A constant and regular ether dropping is essential as deep levels of anesthesia are reached much more rapidly than in open administration. For recovery the patient is given six full breaths of carbon dioxide and is allowed to inhale, with the resultant increased respiration, an atmosphere rich in oxygen. When atropine only has been used in premedication, the patient leaves the operating room phonating with his essential reflexes present and is usually awake in a further sixty to ninety minutes. When morphine is used, the final recovery is delayed. The method depends only on facts, the actual technic can therefore be varied infinitely to suit the individual requirements of any anesthetist.

Intensive Iron Therapy in Combined Sclerosis—Sargent presents a case of combined sclerosis without anemia. On admission to the hospital there was marked weakness in both arms and legs, and the patient could not walk without help. Any attempt to walk was accompanied by gross ataxia. Indefinite areas of anesthesia were found on the forearms, legs and abdomen. The abdominal reflexes were all absent. Knee jerks and ankle jerks were exaggerated, and a bilateral extensor response was present. There was an additional loss of all positional sense in the toes, and the sense of vibration was much impaired in both legs. A test meal showed complete achlorhydria in all specimens and an excess of mucus in the resting juice, which was of small quantity. The stomach emptied in one and a half hours. The blood count was red cells 4,960,000 per cubic millimeter, white cells 7,000 per cubic millimeter, hemoglobin, 88 per cent, color index, 0.9, and the size of the cells was normal. The cerebrospinal fluid tests were all normal, and a roentgenogram of the spine revealed no lesion. The patient was treated with palliative measures such as massage and exercises, for five weeks, but he became steadily worse. Pills of ferrous carbonate 150 grains (9.85 Gm.) a day, were now given, massage was discontinued and no other accessory treatment was allowed. There was an increase in the strength in the legs about three weeks after the iron treatment was begun, the tinglings grew less and the girdle pains disappeared. When walking was first attempted it was impossible to keep the patient on his feet because of his gross ataxia and loss of the positional sense of the feet. Ten weeks after beginning treatment he was able to go home and to walk a little unsteadily by himself. He has been attending the hospital at regular monthly intervals since and can now walk well without

aid, even being able to stand for short periods with his feet together and eyes closed without falling. His ataxia is still noticeable when he is made to turn round quickly. All abdominal reflexes and ankle jerks are present, the knee jerks are not exaggerated, and areas of anesthesia are now difficult to detect. The vibration sense in the legs has improved. The blood picture is red cells, 5,460,000 per cubic millimeter, hemoglobin, 95 per cent. A bilateral extensor response is still present. The patient continues to take a daily dose of 100 grains (6.5 Gm.) a day of pills of ferrous carbonate and has now been under treatment for more than six months.

 Agranulocytic Angina with Septicemia G S Erwin—p 1234

Method for Enumeration of Blood Platelets—In his modification of Flossner's method of counting blood platelets, Cumings adds mercuric chloride to Tyrode's solution without the dextrose to give a strength of 1/10,000 in order to prevent any bacterial growth, five parts of this are added to one part of 1 per cent sublimated saline solution immediately before use and without filtering either fluid. Blood is obtained from the ear by pricking through a drop of the diluting fluid and allowing the blood to flow directly into the diluting fluid without using any local pressure. The contents are thoroughly mixed with a rod or glass tubing coated with petrolatum. The exact degree of dilution is that which, by experience, is shown to give the greatest ease of enumeration. The ear is carefully dried and blood taken for a red blood corpuscle count. A drop of the diluted blood is placed in a counting chamber, and the coverslip applied. After the red cells and platelets have settled the platelets are counted against the red cells, a thousand of the latter being enumerated. It is convenient to have about 150 red cells in a field. The author has not observed any clumping of the platelets, red cell clumping has occurred only in one case of hemorrhagic purpura, and no red cell degeneration has been observed in some hundreds of counts, even when kept for twenty-four hours. His observations confirm those of Flossner and have given a total count of about 400,000 per cubic millimeter after keeping the diluted blood for three hours. The author suggests adding brilliant cresyl blue to Tyrode's solution as an alternative to Toisson's solution for the diluting of blood in performing red and white blood corpuscle counts.

Spondylolisthesis—Burns inserted a graft from the front through the body of the fifth lumbar vertebra and the fifth intervertebral disk into the sacrum in a case of spondylolisthesis. The patient, a boy aged 14 had had pain in the small of the back and in the calves after jumping from a height three months previously. Roentgenography showed that there was a fracture in the laminae of the fifth lumbar vertebra between the roots of the upper and lower articular processes, and that the body of the fifth lumbar vertebra had slipped forward. A plaster bed having been made previously, the operation was performed. The patient was placed in the Trendelenburg position, and the abdomen was opened by a left paramedian incision. The intestine was packed off and an incision was made through the posterior parietal peritoneum. The anterior aspect of the fifth lumbar vertebra was cleared by blunt dissection and the left common iliac vein was gently retracted upward and carefully guarded. A hole was drilled almost vertically downward. A graft was then taken from the tibia and driven home with a punch. The posterior peritoneum was then sutured and the abdomen closed. The convalescence was uneventful. The boy was allowed to walk two months after the operation and had no pain. It is possible that the inter

vertebral disk is not the ideal situation for a graft, in that the graft might become absorbed, but roentgenograms show that this is not the case after seven weeks. Should it become absorbed, a steel pin can be used instead.

Intestinal Tuberculosis—McLaughlin divides the methods of early diagnosis of intestinal tuberculosis into radiologic, clinical and laboratory. He groups the methods of treatment under four headings: heliotherapy and high vitamin diet, dietetic, medicinal and symptomatic, and surgical. He believes that the prevention of secondary intestinal tuberculosis depends primarily on the early diagnosis and successful treatment of the pulmonary tuberculosis. The patients should be warned against swallowing the sputum, as this is the chief mode of infection of the intestine in human tuberculosis. Constipation should be avoided and any catarrhal condition of the intestine should be treated. Patients who show achlorhydria should receive regular doses of hydrochloric acid, although the acid has little or no antiseptic action against tubercle bacilli, when achlorhydria is present the ulcers are said to occur higher in the ileum and jejunum. The general resistance of the patient to infection should be built up by an adequate diet and particularly by a large supply of vitamins A, C and D, in the form of cod liver oil and tomato juice or orange juice. All patients with pulmonary tuberculosis should be given the high vitamin diet as a routine measure. At Ray Brook Hospital, every patient with pulmonary tuberculosis takes half an ounce of cod liver oil and 3 ounces of tomato juice after each meal, and as a result the incidence of tuberculous enteritis is considerably lower than before the procedure was adopted.

*The Quantitative Wassermann Reaction as a Guide to Treatment of Syphilis. Preliminary Communication. J Love and Hildred M Butler—p 727
History and Elimination of Hookworm at Nauru. Short Note. A M B Grant—p 733
Indications for and End Results of Tonsillectomy. R H Beltington—p 734

Wassermann Reaction and Syphilis—In an endeavor to make the Wassermann test more strictly quantitative, Love and Butler increased their dilutions of the patient's serum to include 1:40, 1:80 and 1:160 as well as the 1:5, 1:10 and 1:20 already in use. In order to save both time and reagents all serums were first tested in a dilution of 1:5 only. Those showing complete fixation at that dilution were then tested over the whole range. No evidence of zone phenomenon was obtained in 5000 tests in which each serum was tested in dilutions of 1:5, 1:10 and 1:20. When fixation was not complete in any tube it was found sufficiently accurate to determine with the naked eye the proportion of cells unlysed by comparing the tube with the controls and thus to determine in what dilution complete fixation would have occurred. When readings were made in this way, and also from dilutions at shorter intervals they were so close as to lead the authors to believe that this possible error would not significantly alter the results. The reciprocal of the degree of dilution giving complete fixation was the Wassermann index of the serum tested. A chart similar to a Vernes chart was prepared on which the Wassermann index was plotted against time the treatment given also being shown. In this way a chart was obtained that indicated the severity or degree of syphilization of the patient at any given time and the progress of the case and the response to treatment. The authors present ten such charts showing the progress of

the Wassermann reaction when treatment is instituted at the various stages (that is, primary, secondary or tertiary) of the disease, and they think that they furnish them with a plain and graphic guide to treatment.

Tuberculosis of Mesenteric Glands—Chang gives the histories of six cases of tuberculosis of the mesenteric lymph nodes in which serious gastric complications occurred and intrinsic organic disease of the stomach was simulated. Accurate diagnosis was impossible prior to the exploratory laparotomy or postmortem examination. Complete recovery took place in all four patients in whom relief of the pyloric obstruction followed gastro-enterostomy. There seemed to be little doubt that one of the other patients would have been similarly benefited had he consented to the operation. The other death was attributable to disseminated tuberculosis. Serious complications do not necessarily impair the prospect of a clinical cure, provided they are successfully combated. As the treatment of this condition, like the treatment of tuberculosis in general, depends mainly on good hygiene and dietary management, it necessitates, as a prerequisite, early correction of any dysfunction of the digestive tract. Laparotomy offers the only chance of relieving gastric obstruction of this type and should always be resorted to, not only for diagnostic but also for therapeutic possibilities. This generalization applies to most cases of pyloric obstruction regardless of the apparent etiology. Removal of the diseased gland is not necessary and may be attended with risk. It was not attempted in any of the author's four patients who were operated on.

*Id. Report II. Observations Made After the Injection of Some Substances in Duodenum. K Shi—p 26
Influence of Fat Soluble Vitamin on Amounts of Cholesterol Bodies in Bile in Rabbits. S Kusaka—p 31

Outflow of Bile—According to the experiments of Shi, the intravenous injection of from 0.3 to 0.4 cc of a 1 per cent solution of pilocarpine hydrochloride causes in dogs an increase of the internal pressure of the gallbladder, of the excretion of bile of the tension of the duodenum and of Oddi's muscle, and then of the outflow of bile containing bladder bile. The intravenous injection of atropine causes a decrease of the internal pressure of the gallbladder, of the excretion of bile, of the tension of the duodenum and of Oddi's muscle, and then of the outflow of the bile. The intravenous injection of epinephrine causes a temporary decrease in the internal pressure of the gallbladder, in the tension of the duodenum and of Oddi's muscle and a temporary outflow of liver bile. The intravenous injection of solution of pituitary causes a slight increase of the internal pressure of the gallbladder, depression of the tension of the duodenum and of Oddi's muscle, and an outflow of bile containing bladder bile.

Outflow of Bile After Injection of Substances into Duodenum—Shi states that the infusion of milk or peptone into the duodenum of a dog causes an increase of the internal pressure of the gallbladder, a depression of the tension of Oddi's muscle and of the duodenum and, therefore, an outflow of bladder bile. The infusion of the duodenum with magnesium

sulphate causes a depression of the tension of Oddi's muscle and of the duodenum and then the outflow of bile containing bladder bile, without causing an increase in the internal pressure of the gallbladder

Benzene Poisoning—Emile-Weil states that the increased use of benzene in industries has resulted in an increase of benzene poisoning. Benzene intoxication from inhalation of the benzene vapors most frequently results in injury to the blood and the hematopoietic organs. The injury may cause not only hypoplasias of the erythrocytic or leukocytic system but hyperplasias of the leukocytic system as well. The anemias produced by benzene vary from latent or light forms to severe cases of pernicious anemia. The author thinks that the hemorrhagic tendency which often accompanies the light anemias of benzene intoxication possibly contributes to the production of the anemia, and that in all events it is a prodromal sign of a syndrome of a grave anemia with purpura hemorrhagica, which is best called aleukemia hemorrhagica. This is the most common form of severe benzene intoxication. It presents no differences from the hemorrhagic purpura caused by gold salts or arsphenamine. Death occurs within a few days in the severe cases, when the poisoning is less severe, slow recovery may occur. Benzene poisoning may have a very early effect on the leukocytes. Persons in apparent good health, having no clinical signs of anemia, may have a slight leukopenia, and cases have been reported presenting a light anemia and a severe leukopenia, but no true agranulocytic syndrome has been described as yet. The occurrence of hyperplasias as a result of benzene intoxication is rare, but both acute and chronic cases of leukemia have been reported. Lignac was able to produce some cases of leukemia and some of lymphosarcoma in mice by administration of benzene. This contradictory effect of benzene does not seem so strange in view of the fact that roentgen rays may produce either aplasias or hyperplasias of the blood and hematopoietic organs.

 Influence of Anesthesia on Alkali Reserve S. Schere—p. 1781

Influence of Anesthesia on Alkali Reserve—Schere reviews the literature on the role of anesthesia in the changes of the alkali reserve observed after surgical interventions. He found that all authors agree that general anesthesia, especially if performed with chloroform, brings about an intoxication and a state of shock producing a lowering of the alkali reserve. Various theories, such as the liberation of phosphoric acid by the muscles and its storage in the blood with free elimination of alkaline ions, the increased production of lactic acid, and the inhibition of the respiratory center under the influence of anesthesia, have been given as an explanation for the appearance of postoperative acidosis. However, there has not been a satisfactory explanation, but the authors agree that it is a "non-compensated" acidosis. Cannon believes that there exists a great parallelism between the fall of the blood pressure and the diminution of the alkali reserve. Schere believes that the arterial hypotension which follows general and spinal anesthesia is the cause of acidosis observed after surgical interventions performed with those types of anesthesia. The author studied the postanesthetic changes of the alkali reserve in children. He determined the maximal, mean and minimal values of the alkali reserve in thirty-five children, immediately before and after the administration of the anesthetic, and also twenty-four hours and forty-eight hours after the operation. The operations performed in those children were of various kinds. Ether was used in twenty-two cases, chloroform in eight, and local anesthesia in five. The author concludes that general anesthesia

by ether or chloroform produces a great lowering of the alkali reserve, more pronounced in the case of chloroform than in that of ether, and that the return of the acid base equilibrium to normal is more rapid with ether than with chloroform, being normal forty-eight hours after the operation. This does not happen in children who receive chloroform anesthesia. Local anesthesia does not produce any variation of the alkali reserve.

 Contribution to Ambulatory Treatment of Varicose Ulcers of Leg J. Marx—p. 181
 Acute Appendicitis in Advanced Age W. Arnold—p. 187

Pneumoroentgenography of Knee Joint—Oberholzer states that an ordinary roentgenogram of the knee joint gives but little information regarding the menisci, Hoffa's fat bodies, the crucial ligaments and the relations of the capsule. Arthroendoscopy after the injection of nitrogen gas, as practiced by Bircher, has not given the desired result. The so-called positive contrast mediums capable of producing shadows in a roentgenogram, such as iodized oils have the drawback of giving shadows too thick for a finer study of anatomopathologic details. Injection of negative contrast mediums, such as nitrogen, oxygen or atmospheric air, proved of value in recognition of lime and cartilaginous loose bodies, as well as in recognition of Hoffa's disease. In order to combine the advantages of both the positive and the negative contrast mediums, a combination of the two was attempted. A small amount, 2 or 3 cc., of the positive contrast medium was injected into the knee joint and distributed by massage, after which the joint was filled with oxygen gas. The positive medium coats the joint capsule, the menisci, the crucial ligaments and the cartilage. The introduction of the negative medium further intensifies the delineation of structures. Of the positive mediums experimented with, sodium iodide was found too irritating to the synovial membrane, while sodium bromide did not give sufficient contrast. Iodized oils were incapable of fine division and frequently clumped into masses which gave rise to erroneous interpretations. Iopax proved to be too painful. Methiodal seemed to possess all the qualifications required. It is nonirritating, is capable of fine division and gives satisfactory shadows. In Bircher's clinic, 700 arthropneumoroentgenograms have been carried out by the use of the combination of methiodal and filling of the joint with oxygen gas. The author concludes that pneumoroentgenography of the knee joint is a safe procedure. It gives a clear presentation of the structures of the normal knee. It enables one to recognize in a high percentage of cases injury to the menisci, the crucial and lateral ligaments, the joint capsule and the Hoffa bodies. The diagnosis of Laeven's disease and of osteitis dissecans is placed on a more secure basis. Diseases of the capsule can be diagnosed with frequency. Follow-up observations with this method demonstrated a partial or complete regeneration of a resected meniscus in a majority of cases after a lapse of about two years. The method has its limitations and not all the types of trauma or joint disease are rendered recognizable by it.

Ambulatory Treatment of Varicose Ulcers of Leg—Marx reports on the use of the rubber sponge in the ambulatory method of treatment of varicose ulcers of the leg. The method consists in cleansing the ulcerated area and covering it with a layer of dry gauze one finger thick over which a rubber sponge, reaching for two finger breadths beyond the ulcerated area, is applied. The sponge is secured in place by an elastic bandage reaching from the toes to the knee. The patient is encouraged to walk and to exercise his legs. The dressing is changed once every two days. The skin in the neighborhood of the ulceration remains dry because of the absorbing quality of the rubber sponge. Circulation in the limb is improved because of the muscular activity and the effect of elastic compression by the sponge on the venous return. The method was applied in thirty-four patients with indolent ulcers which proved refractory to treatment with rest in bed or Unna's paste boot. Complete healing was brought about in all cases in from three to twelve weeks.

Acute Appendicitis in the Aged—According to Arnold, acute appendicitis in the aged is a relatively frequent disease. Among 2,257 patients operated on for acute appendicitis in the clinic of H. Klose in Danzig, 172 were past the age of 50, an incidence of 7.6 per cent. Old age, therefore, is no argument against a diagnosis of appendicitis, on the contrary, one should always consider it in instances of obscure abdominal disease in the old. One should not be misled by an incomplete picture and the frequent absence of a severe general reaction. Accurate history and a careful evaluation of all symptoms constitute the most important diagnostic safeguards against error. Acute appendicitis of the aged appears frequently as a destructive gangrenous process. The grave pathologic observations are often in striking contrast to the relatively mild clinical picture. The author found that a number of his patients presented a clinical picture similar to that seen in the young. In some, the disease picture was characterized by the predominance of local symptoms over the general, and the gravity of the situation was frequently unrecognized by the doctor and the patient. This was particularly true of obese patients. In some, the general symptoms of an acute attack found so little expression that the patient became aware of the situation only after perforation had taken place. Finally, there was a group in which correct diagnosis was hardly possible and which was recognized only at operation. These patients are often operated on because of a diagnosis of ileus. Contrary to the experience of other authors, the so-called neoplastic form of appendicitis, as well as appendicitis in a hernial sac, did not play a prominent part in the author's material. Conservative treatment of appendicitis in the aged is even less justified than in the young, and early operation is productive of excellent results just as in appendicitis of the young. An age limit does not exist for the early operation. The author is opposed to inhalation anesthesia and finds spinal anesthesia best suited to these cases.

Pancreatropic Action of Extracts from Anterior Lobe of Hypophysis—According to Anselmino and his associates, clinical as well as anatomopathologic observations indicate a relation between the anterior hypophysis and the pancreas. In acromegaly, for instance, there is frequently a considerable increase in the pancreas, and in young diabetic patients a shrinkage of the eosinophil cells of the anterior hypophysis has been noted. In order to gain more insight into this interrelation, the authors resorted to animal experiments. Young rats were given from six to seven injections of extract of the anterior lobe of the hypophysis and then were killed. The histologic examination of the pancreas of these animals revealed an enlargement of the islands of Langerhans and a fusion of several island complexes, also an increase in young newly formed islands. The authors are as yet not in a position to state whether or not these changes are the result of the action of a special substance. They only gained the impression that the pancreatropic substance, although it largely resembles the gonadotropic and the thyrotropic substances in its physical and chemical properties, does not seem to be identical with them.

Increase in Rest Nitrogen in Serious Cases of Poisoning—Popper and Schechter point out that in cases of severe

poisoning the rest nitrogen of the blood is sometimes increased to a degree that does not correspond to the clinical aspects. They determined the rest nitrogen of a number of patients with severe poisoning. In the majority of cases the poisoning was caused by carbon monoxide, compound solution of cresol or barbituric acid preparations. In the patients in whom the poisoning was mild, the rest nitrogen values were within normal limits while in the comatose patients the rest nitrogen reached from 90 to 100 mg per hundred cubic centimeters, but after a short while, sometimes within a few hours, the rest nitrogen decreased again to 40 mg. The rise in the rest nitrogen was always accompanied by an increase in the urea content. However, indican and the other substances retained in cases of renal insufficiency were not increased. The authors point out that in patients in whom the increase in rest nitrogen is the result of renal insufficiency, as for instance in poisoning caused by corrosive mercuric chloride, the increased rest nitrogen requires a much longer time to recede than in the cases studied by them, and renal disturbances were not demonstrable in their patients. They show that the increase in the blood urea is not caused by a disturbance in the elimination of urea but is rather due to the fact that the organs of urea production and storage, that is, primarily the liver, give off larger amounts. But since there are no signs of impairment of the liver the authors conclude that the increase in the urea, as well as in the rest nitrogen, is caused by a disturbance in the central nervous regulation.

Acute Diarrheal Disturbances in Nurslings—De Rudder says that three factors should be considered in the treatment of a nursling with diarrhea: the general condition of the child, the symptoms accompanying the diarrhea and the probable etiology of the diarrhea. In discussing the general condition the author points out that the age of the nursling is of great importance. Dyspepsias occurring during the first three months of life are always serious. With advancing age the conditions become more favorable and the treatment more simple. Moreover, it is not the same whether nutritional disturbances develop in a breast-fed infant or in a bottle-fed infant. Dyspepsias of breast-fed nurslings are generally much milder than those of bottle-fed nurslings, and the author emphasizes that dyspepsia in a breast-fed infant is never an indication for the termination of nursing at the breast. The seriousness of a dyspepsia also depends on the fact whether it develops in a well nourished child in a dystrophic one, or in one with atrophy. Of the symptoms that accompany diarrhea the author discusses loss of turgor, vomiting and signs of toxicosis. A knowledge of the etiology is likewise important in the proper management of dyspepsia. The author discusses alimentary dyspepsia, which may be caused by errors in care and feeding, and infectious dyspepsia of the parenteral type developing in the course of infections outside the intestinal tract, for instance of the respiratory tract or of the ear. It is evident that this type of dyspepsia requires a different treatment than does the alimentary type. The author designates as enteric dyspepsia in which the infection is localized in the intestinal tract and he points out that this form may be caused by many different pathogenic organisms. The treatment of all acute diarrheas of nurslings should be done in three stages: first a hunger period during which weak tea and later thin gruels are given, then the period of curative diet, during which the nursling receives diluted milk with the addition of carbohydrates or of protein preparations, and finally the change to a normal diet. The author gives advice on the treatment of the various forms of dyspepsia.

Agranulocytosis Following Brain Trauma — Bingel reports the history of a man, aged 59, in whom agranulocytosis became manifest following a traumatic hemorrhage of the brain, and who died a short time later. The anamnesis, which revealed a past history of articular disturbances and of excessive drinking, indicates that two years previous there had already been symptoms of agranulocytosis. The necropsy showed a beginning cirrhosis of the liver and, since there are indications for a connection between liver and bone marrow (liver therapy of anemia), it is likely that the cirrhosis of the liver played a part in the etiology of agranulocytosis. Moreover, it is known that an agranulocytic reaction frequently occurs in articular disturbances. However, the author is unable to say whether in this case there was a causal connection between the agranulocytosis and the articular disturbances, and he only wishes to call attention to such a possibility. He assumes that in the reported case the agranulocytosis was elicited by the brain trauma by way of the mobilization of a latent infection (attack of chills on the evening of the day of a fall on the head). The rapid succession of trauma and agranulocytosis indicates their causal connection, and death would thus be a result of the accident.

Moor Baths and Absorption of Iodine Through Skin — The moor baths employed by Anthes and Salzmann were prepared by mixing 50 Kg. of bath moor with 50 liters of hot water, so that the bath had a temperature of 39 C (102.2 F), to which from 5 to 50 Gm. of potassium iodide was added. A bath lasted twenty minutes. Baths without the addition of moor or of iodine salts served as controls. The iodine content of the blood and of the urine was determined, and it was found that after a moor bath to which potassium iodide had been added the iodine content of the blood was increased. The maximum of the iodine content of the blood was reached in from one and a half to three hours. After four and a half hours the values were again normal. The concentration of the baths had no influence on the iodine content of the blood. The iodine was not eliminated in the urine, and it is probable that it was deposited in the tissues.

Treatment of Acute Articular Rheumatism — Streubel maintains that acute articular rheumatism is the result of a streptococcal infection, the particular streptococcus being not yet identified. He shows that, in patients in whom articular rheumatism follows a tonsillitis, painting of the tonsils with alcohol or with spirit of tannin is effective. This procedure is used to prevent further dissemination of bacteria and of their toxins. The alcohol or the spirit of tannin is applied three times daily and counteracts the fever and the articular pains within a comparatively short time. However, the increase in the defensive power of the organism is also an important factor in the treatment of articular rheumatism. Since a specific serotherapy is not possible, the author recommends non-specific irritation therapy and states that he has obtained good results with the intramuscular injection of a turpentine preparation. The injections are given every two or three days into the gluteal muscle. In adults 1 cc. is administered and in children 0.05 cc.

Simple Method for Determination of Blood Sedimentation — Steiger employs a leukocyte pipet for his simplified sedimentation test. His method is as follows: Citrate solution

is drawn up to mark 5 of the leukocyte pipet and is then blown out. Then the blood, which he advises taking from the finger rather than from the ear, is drawn up to mark 1 and is blown into the drop of citrate solution. This mixture is stirred and drawn up again to mark 1. Then the pipet is closed by means of paraffin and is put in the vertical position, and after one or two hours the result is read. The readings of course do not correspond to those of the standard method, for a pipet of 60 mm. cannot show a sedimentation of 50 mm. However, the author thinks that in the end it is the same, whether the sedimentation is given according to Westergren with 20 and 40 mm. or according to this "micromethod" with 15 and 28 mm. He stresses the following as the advantages of his micromethod: It is simple, dispenses with complicated apparatus and can be employed in small children. Moreover, since a small amount of blood is sufficient, puncture of a vein is unnecessary, which is important, because the sedimentation test, to be valuable, requires repetition.

Blood Picture in Icterus Neonatorum Familiaris Gravis — Altitzoglou points out that, among the various forms of icterus in the newborn, icterus gravis is of especial importance because of its serious consequences for the family. The statement that a similar case has already been observed in the family, particularly if in the same generation, is of greatest significance for the diagnosis. However, isolated cases are possible, and it is important that the first case occurring in a family be recognized, the more so since an early diagnosis will make possible therapeutic measures which are often helpful in a disturbance that frequently ends fatally. The author shows that erythroblastosis is a characteristic symptom of icterus neonatorum familiaris gravis. Since erythroblastosis is physiologically present in the newborn, it may be difficult to estimate this symptom unless it occurs in an extreme form. However, erythroblastosis has a pathologic significance if it increases during the first few days of life. In doubtful cases it is advisable to count the normoblasts in addition to taking into consideration the anamnesis and the clinical symptoms. The author cites normal values from the literature and from his own observations. He emphasizes that the early diagnosis of this form of icterus is important because an early diagnosis will make possible a blood transfusion, which may cure this frequently fatal disorder.

Constitutional Influences and Nutritional Disturbances — Schuppers' report is based on observations on 691 nurslings with severe nutritional disturbances. He points out that according to leading pediatricians the causes of nutritional disturbances are classified into three groups, alimentary, infectious and constitutional. He thinks that too many manifestations are ascribed to constitutional factors purely because of the want of an adequate explanation. He tries to determine the role of constitutional factors in the pathogenesis of serious nutritional disturbances, and he evaluates particularly the significance of so-called constitutional hydrolability. His definition of constitution coincides more or less with that of von Vershuer, according to which it includes all factors that determine the status of the nursing at birth. He designates these factors as endogenic and, in contradistinction to it, terms all others, that is those that influence the nursing after birth, as exogenic. He finds that endogenic factors played a part in about 25 per cent of the nurslings with nutritional disturbances. He thinks that this figure may be too low, since the data regarding the nearly 200 cases with fatal outcome are insufficient. Nevertheless, constitutional factors play a part in

the smaller number of cases. He discusses constitutional hydro-lability and concludes that it is the result and not the cause of the reduced resistance in nurslings and that the two have the same cause. Hydrolability exists because the child is ill and not vice versa. The author states his theory about hydro-lability as follows. Hydrolability does occur occasionally as a diathesis, but as such it does not represent a deciding factor in the etiology of nutritional disturbances. He believes that as a symptom of nutritional disturbances hydrolability may be serious, and that it is a sign of grave changes.

Early Sign of Chickenpox.—Lade has found that many children have a diarrheal or an extremely thin stool two weeks before the manifestation of the eruption of chickenpox, and he thinks that this observation should be an inducement to isolate such a child. The diarrheal stool has also a certain significance for the still disputed question of the port of entry of the chickenpox virus. The author thinks that it indicates the intestinal route.

Raw Apple Diet in Intestinal Disorders.—Hartwich states that Heisler's report on the favorable effect of the raw apple diet on intestinal disorders was taken up almost exclusively by pediatricians, who corroborate its beneficial effect in intestinal disorders of children while it found little application in the treatment of intestinal disturbances of adults. He therefore reports his observations with the apple diet on adults. He treated forty-six cases of gastrogenic diarrheas, acute enteritis and gastro enteritis, dysentery and paratyphoid, and on the basis of his observations he recommends the raw apple diet for the treatment of such cases. He found that the diarrheas are promptly arrested and that the stools soon become negative in infectious intestinal disorders. He states that he employed the grated pulp of ripe, peeled raw apples. The apple diet usually satisfied the hunger and thirst of the patients completely and it became necessary to give some tea during the night only in extremely dehydrated cases. The daily quantity of apples varied between 0.5 and 1.5 Kg. In most cases the apple diet was followed by a day of restricted diet and after that, the patients were given the general hospital diet. The author discusses the various theories of the mode of action of the apple diet.

Apple Diet in Young Nurslings and Small Children.—Urbanitzky points out that the favorable experiences obtained with the Heisler-Moro apple diet in intestinal disturbances of children beyond the nursling age induced her to try the apple diet also in nurslings. But because apples that are suitable for the raw apple diet are not available the year round she used a pure apple powder. She employed it in ten nurslings of less than 6 months in twelve of less than a year and in twenty-five of less than 2 years. The disturbances were of various types and origins being acute and subacute nutritional disturbances, infectious enteritides, nutritional disturbances of parenteral origin and manifestations of intoxication. Disorders of such diverse origin responded equally well. The youngest nurslings first received tea with a 4 per cent addition of the apple powder and later their milk mixture with an addition of from 5 to 6 per cent of apple powder. With this treatment the stools usually became normal on the third or fourth day.

The number of calories was reduced to about half during the treatment in the severest cases and to about two thirds in the less severe cases. In older nurslings and in small children, the apple powder had to be given only for two or three days, and sometimes only for one day. In cases of intoxication, protein milk was given in addition to the apple powder, beginning with the second or third day.

Contralateral Adductor Reflex in Absence of Patellar Tendon Reflex.—Herschmann noted a peculiar reflex phenomenon in a man, aged 48, who was operated on because an atypical syringomyelia was assumed. The patient had a spastic paresis of the legs, which has been improved since the operation although there still exist, particularly in the region of the left lower extremity, considerable hypertonia, spontaneous movements and a spastic-paretic disturbance. The Babinski and the Oppenheim reflexes are positive on the left side and the achilles tendon reflexes are increased on both sides. The percussion of the achilles tendon elicits not only a plantar flexion of the foot but also a lively twitching of the adductor group of the same side. The patellar tendon reflex of the left side is greatly increased. Percussion of the region of the medial condyle elicits on the left side a lively adductor reflex, which partly involves the adductor group of the right side. An attempt to produce the adductor reflex on the right side results in a slight twitching of the adductors of the left side, whereas the group on the right side responds hardly at all. This proves that the crossed adductor reflex predominates. However, the phenomenon to which the author desires to call attention is that the patellar tendon reflex of the right side is absent. Percussion of the patellar tendon of this side produces in the adductor group of the left thigh an extremely lively contraction. Thus, the phenomenon in question is a crossed adductor reflex, which is produced by the percussion of the patellar tendon of the side on which the patellar tendon reflex is absent. The author observed the same phenomenon also in another patient in whom neurologic examination revealed the abolishment of the patellar tendon reflex, of the adductor reflex and of the achilles tendon reflex on both sides. He discusses various theories of the pathogenesis of the crossed adductor reflex.

New Therapeutic Principle in Exudative Disturbances.—Ried calls attention to biologic actions shown by inorganic substances, particularly by certain salts after they have been irradiated. The type of action is dependent on the quality and the quantity of the rays on the aggregate state of the substance (solid, fluid, gaseous, crystalline or colloidal) during irradiation and on the distance between the source of rays and the substance. Irradiation experiments were performed primarily on salts the chemical state of which was not changed by the irradiation. The author thinks that the new biologic action of irradiated salts is due to the energy emitted by the salts which he assumes to be beta rays. The result of biologic experiments on animals induced him to attempt a therapeutic utilization of irradiated salts. He employed them in the form of baths. A concentrated solution of potassium salt was exposed for fifteen minutes to the light of a mercury vapor lamp following a preliminary exposure to red rays. This irradiated solution was then used for baths that had a concentration of 0.05 per cent a hydrogen ion concentration of 7.75 and a temperature of 28°C. (95°F.) and lasted from fifteen to twenty minutes. Occasionally partial or total pricks were

employed instead of the baths, the concentrations of the packs varying in different cases. The author thinks that neither the temperature nor the concentration of the baths would be capable of producing the therapeutic effects that were obtained and that, as subsequent sweating was avoided in order not to eliminate again the traces of salt which had been adsorbed, sweating can also be excluded as a therapeutic factor. He concludes that the therapeutic action of the baths must be due to the ray action of the salt solution. He reports the histories of several patients in whom about twenty baths produced considerable improvement in conditions such as polyarthritides and spondylarthritides and in a case of exophthalmos following a septic disorder. He believes that the baths with the irradiated solution of potassium salt will not remain without effect in other exudative processes. At any rate, in particular processes of various origins that prove refractory to other treatments the baths with the irradiated salt solution usually give good results.

Early Tuberculous Infiltrate—Observations from 1926 to 1931 convinced Alexander that patients with early tuberculous infiltrates should receive institutional treatment as early as possible. He found that, if all external irritation is kept away from them, spontaneous and permanent improvement may be expected in a large percentage of the patients. Beginning cavernization and even completely formed round caverns do not always necessitate collapse therapy immediately. Careful clinical observation, particularly examination of the sputum, will generally reveal, within the first or at the latest within the second month, whether an expectant attitude can be assumed or whether active therapy is advisable. If these principles are followed, the prognosis of the early infiltrate is favorable, that is, there are prospects of recovery in approximately 90 per cent of the cases.

Phrenic Exeresis—Naegeli and Schulte-Tigges evaluate phrenic exeresis on the basis of their experiences in 314 cases. In discussing the technique of exeresis they point out that, in case of considerable adhesions, twisting of the nerve should not be done with too much force, as this may result in injuries, but resection should be resorted to and care should be taken that the branches of the nerve are also removed. The authors observed the complications of phrenic exeresis, against which some observers have warned only in mild forms and generally only for a short time after the operation. The authors cannot corroborate the observation that phrenic exeresis is most effective in processes of the lower lobes but rather found that those in the median portion of the lung are influenced most favorably. They think that, if after two or three months the exeresis has not produced satisfactory results, other surgical methods should be resorted to. They advise more use of the temporary exclusion of the phrenic nerve by means of crushing, freezing or alcohol injection. Crushing of the phrenic nerve is particularly

helpful for temporary exclusion. It interrupts the nerve conduction for from four to six months, provided that eventually existing accessory phrenic nerves also are excluded.

- *Continued Investigations on Circulatory Conditions in Varices and Their Connection with Ulcer and Eczema of Leg H. Haxthausen—p. 233
 *Investigations on Kidney Function in Patients with Heart Disorders A. Brems and F. Nielsen—p. 266

Circulatory Condition in Varices—Haxthausen states that the results of his later as well as his earlier investigations point to a close etiologic relation between filtration edemas and cutaneous complications in varices and that an explanation of the pathogenesis of these complications on this basis harmonizes with clinical experiences regarding their appearance.

Kidney Function in Heart Diseases—Brems and Nielsen found that the results of creatinine and urea clearance determinations and of Strauss's concentration test agreed both in normal persons and in patients with renal or cardiac disorders. Most patients with marked heart insufficiency and a considerable number with symptoms of stasis without marked insufficiency give creatinine and urea clearance values below the lowest normal limit. There was no constant agreement between the clinical judgment of the condition of the heart and the results of the kidney function tests. No certain difference was seen in the kidney function in cardiac patients with increased and with normal blood pressure.

 Exploration Ointment Dsk. H. Wulff—p. 845
 New Hemostatic J. O. Jacobsen—p. 845
 Gymnastic Therapy (German Points of View) A. Faber—p. 846

Clinical Significance of Diastasia—Foged made 1247 analyses of the urinary diastase in 175 patients with different forms of jaundice. In patients with hepatitis and cancer of the pancreas the diastase concentration does not exceed the normal, but pathologically increased values are seen in more than half of the patients with stone in the choledochus. In cases of jaundice presenting diagnostic difficulties an increased urinary diastase is thus considered as a probable indication of stone in the common bile duct, although a normal urinary diastase does not testify against this condition.

Acute Febrile Syphilitic Meningitis—Clemmesen and Schrøder's patient aged 25 presumably infected with syphilis ten months earlier gave the picture of acute meningitis with fever. Changes were found in the spinal fluid, and the Wassermann reaction was positive in both blood and spinal fluid. The symptoms disappeared on administration of antisyphilitic treatment. The authors state that acute syphilitic meningitis, while rare, occurs in children and adults, most often between the age of 20 and 30 generally appearing from two to twelve months after the infection, although a latent period of several years has been observed. With timely antisyphilitic therapy the prognosis is usually good. In cases of meningitis, syphilis should be borne in mind as the possible cause and the Wassermann test made on the spinal fluid.

THE EPIDEMIOLOGY OF LOBAR PNEUMONIA

A STUDY OF THE PREVALENCE OF SPECIFIC STRAINS
OF PNEUMOCOCCI IN THE NASOPHARYNX OF
IMMEDIATE FAMILY CONTACTS

WILSON G. SMILLIE, M.D.
BOSTON

An attempt was made in this study to clarify certain points in relation to the epidemiology of lobar pneumonia

1 Is any specific type of pneumococcus more prevalent in the immediate family contacts of a case of lobar pneumonia due to that particular type of pneumococcus than in the population at large?

2 Is there any difference in the epidemiologic behavior of the different types of pneumococci?

3 Do certain specific types of pneumococci that are more or less prevalent in the normal population pass more readily from the sick to the well than from normal person to normal person?

4 Are there any measurable environmental factors, such as overcrowding, economic or social status, or seasonal variations, that may influence the ready transfer of a specific type of pneumococcus from the patient to his immediate contacts?

5 Do variations in the individual, such as the age factor or the existence of an acute infection of the respiratory tract in the family, have any appreciable effect on the distribution of specific types of pneumococci to the family contacts of a case of pneumonia?

In an attempt to determine these points, a study was made of the correlation of the prevalence of the various specific types of pneumococci in the throats of the family contacts with the homologous type of pneumococcus isolated from the sputum in a given case of lobar pneumonia. If one type of pneumococcus is much more prevalent in the nasopharynx of immediate family contacts than in the general population, it might indicate that this specific strain was spread readily through direct contact of the patient with a normal person, and this would be suggestive evidence that the particular strain had epidemiologic significance. If, however, the various specific strains of pneumococci are just as prevalent in the community at large as in the throats of individuals in contact with a case of pneumonia due to homologous strains, it would seem that these strains are spread as

readily from normal person to normal person as from the sick to the well and have little or no epidemiologic significance

The unit in these studies has not been the individual or the community but the family. Family epidemics of lobar pneumonia are not a common phenomenon, but the same is true of several other communicable diseases spread by direct contact. A study of the immediate family contacts of a case of pneumonia would seem to be the logical approach to determine the mode of spread of the pneumococcus in the community.

A number of observations have been made of the prevalence of specific types of pneumococci in the nasopharynx of immediate family contacts of pneumonia patients. Notable among these studies are those of Stillman,¹ Rosenau, Felton and Atwater,² and Jacobson.³ These authors were concerned with the familiar original pneumococcus types of Dochez and Gillespie, namely, specific types I, II and III and the heterogeneous group IV. Recently, Cooper⁴ and her co-workers have subdivided the various strains of pneumococci that comprise group IV into a considerable number of specific types. Since a large proportion (from 30 to 40 per cent of all the cases of lobar pneumonia) are caused by pneumococci of group IV, it seemed timely not only to supplement the work of the previous observers in relation to the epidemiology of types I, II and III but also to accumulate data in relation to contacts with cases of pneumonia that are caused by the various types of pneumococci of the heterogeneous group IV.

Only lobar pneumonia was considered in our studies. The diagnosis in each case was made by the clinical picture and by the determination of the type of pneumococcus obtained from the sputum of the patient. The occurrence of the actual cases of pneumonia was reported to us by the various hospitals and private physicians in the city of Boston and environs. The sputum was obtained from each patient and the type determined by standard methods. (The laboratory diagnosis of approved laboratories in the larger hospitals was accepted in some instances.) After the probable causal agent of the case of pneumonia had been determined, the family of that patient was visited and nasopharyngeal cultures were obtained from as many of the immediate family contacts of the patient as possible. Cultures were taken only if there had been contact with the patient during the previous seven days. This interval gives one ample margin, since various authors have shown that a pneumococcus strain, when once estab-

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

lished, usually persists in the nasopharynx of the individual for a considerable period.

The nasopharyngeal swab taken from each contact was placed at once in a tube of hormone blood broth, brought to the laboratory as quickly as possible, and given a quick incubation of three hours at 38 C. This blood broth (0.8 cc.) was then injected into the peritoneal cavity of a mouse. At the same time, a hormone blood agar plate was streaked with material from the original blood broth culture. The mouse was killed after twenty-four hours (if it had not already died) and the heart's blood and peritoneal fluid were streaked on hormone blood agar plates. Strains of pneumococci were isolated and identified in the customary manner. The specific type was determined by serum agglutination, the technic being used that was recommended by Cooper,⁴ who kindly furnished the specific serums. Serums were available for only types I to XIX inclusive at the time the experiment was begun, but these serums are sufficient for the purpose, since they include the great proportion of types of pneumococci that were encountered.

Some of the strains of pneumococci from the original broth culture were avirulent for the mice, or sometimes death of the mouse occurred from other organisms. In these instances it was necessary to return to the blood agar plate which had been made directly from the throat cultures. Thus, some strains of pneumococci were obtained from the plates when no pneumococci had been obtained from mouse cultures. These strains were isolated and identified in the usual manner. A frequent cross check was made also between the type of strains isolated from the mouse culture and that from the original blood agar cultures. My associates and I determined, as have other workers in this field, that there is an agreement in practically every instance between the strains isolated by the two methods.

CONTROLS

Nasopharyngeal cultures were made of a control group of persons in the same manner as in the group of contacts. The controls were selected as nearly as possible from the same economic and social groups as were the contacts, and the cultures were taken during the same seasons of the year. The control group practically equals the contact group in numbers.

EPIDEMIOLOGIC DATA

The study was continued through a period of twelve months to determine the effect of any seasonal variation. Few cases of lobar pneumonia occurred during the summer months, so that the number of contacts that were obtained during this period is small. Information was obtained from each patient with pneumonia and from his contacts in relation to the general economic status and the living conditions that might produce overcrowding and malnutrition. The history of present or recent attacks of acute diseases of the respiratory tract in the family was obtained, including colds, influenza and bronchitis, as well as a history of any previous attack of pneumonia in the patient or in his family.

The virulence (to a mouse) of each strain of pneumococcus that was isolated from a contact or control person was also determined.

TYPES OF PNEUMOCOCCI ISOLATED FROM ACTUAL CASES OF LOBAR PNEUMONIA

One hundred and seventy-three cases of pneumonia were observed during the twelve months period. Since

the primary interest was centered in the contacts of these patients and not in the patients themselves, the information in regard to the patients will be summarized briefly. The data concerning the strains of pneumococci that were isolated from the sputum of these patients are given in table 1.

TABLE 1—Specific Types of Pneumococci (According to the Cooper Classification) Isolated from One Hundred and Seventy-Three Cases of Lobar Pneumonia

Type of Pneumococcus	Number of Patients in Each Group	Deaths
Total	173	29
I	48	8
II	24	9
III	16	3
IV	5	1
V	8	3
VI	3	0
VII	8	0
VIII	12	1
IX	2	0
X	3	0
XI	1	0
XII		
XIII	2	0
XIV	1	0
XV	1	0
XVI		
XVII	3	1
XVIII	7	0
XIX	1	1
Higher types	8	1
Negative	10	1

Table 1 shows that pneumonia due to all types of pneumococci were represented in the series of cases except types XII and XVI. Not one of the groups contains a considerable number except type I and type II. The dispersion is quite striking, for no other group contains more than 5 per cent of the total number except type III (9 per cent) and type VIII (7 per cent).

TABLE 2—Mortality Rate of One Hundred and Seventy-Three Cases of Pneumonia

	Number of Cases	Per Cent of Total Cases	Deaths	Case Mortality Rate per Cent
Type I	48	28	8	16.7
Type II	24	20	9	37.5
Type III	16	9	3	18.7
All other types	75	43	9	12.0

The data of table 1 have been summarized into the four conventional groups of pneumococci (table 2) and it was found that the percentage distribution of the pneumonia due to the various groups is similar to that found by other workers in this field. A somewhat

TABLE 3—Age Distribution in the Cases of Pneumonia

	Birth to 19 Years		20 to 39 Years		40 to 60+ Years	
	Cases	Deaths	Cases	Deaths	Cases	Deaths
Type I	13	1	18	2	17	5
Type II	9	0	18	1	17	8
Type III	2	0	6	0	8	3
All other groups	28	3	27	3	20	3

higher proportion fall in group IV, but this is probably due to the fact that the cases were not limited to hospital admissions but taken from the general practice of physicians as well. The case mortality rate of pneumonia due to type I is much lower than one would expect, but this is due to the fact that many of these patients were given type I pneumococcus serum early.

in their illness. This study has been reported by Heffron.⁵ The low fatality rate in type III pneumonia cases is probably due to the fact that most of these patients were in the lower age groups, for, as Blake⁶ has shown, type III pneumococcus spares the young but is particularly fatal to the aged. The distribution of the cases of pneumonia by age groups is shown in table 3.

When the pneumonia cases are subdivided further into ten-year age periods, one finds an almost equal distribution of the cases in each group—with from twenty to thirty-five cases in each ten-year age period (except the group of 60 years and over, eleven cases). In general, the mortality rate increased with age, the lowest mortality rate was in the group of 20-29 years inclusive, 4.2 per cent, and the highest mortality rate in persons over 50 years, 45 per cent. Pneumonia due to types I, II and III strains of pneumococci were distributed throughout all age groups. None of the specific strains that comprise group IV had any predilection for one age group but were also widely distributed. Type III was extraordinary in that, of twelve patients under 55 years of age who developed the disease, none died, whereas, of four persons over 55 years of age who had type III pneumonia, three died.

So far as these data go, there is no evidence that poor economic status or overcrowded living conditions played any definite part in either the incidence or the mortality from lobar pneumonia.

Seasonal influences, however, played a definite role in the incidence of the cases of pneumonia. Each case was allocated according to the date of onset of first symptoms.

The seasonal distribution of the cases was as follows:

Summer	July 1 to September 30, 12 cases
Autumn	October 1 to December 31, 36 cases
Winter	January 1 to March 31, 64 cases
Spring	April 1 to June 30, 59 cases

No single type of pneumococcus was prevalent in one month only or in one season only, but rather there occurred a general distribution of the various types throughout the seasons.

THE PREVALENCE OF PNEUMOCOCCI IN THE NASOPHARYNX OF INDIVIDUALS IN IMMEDIATE CONTACT WITH CASES OF LOBAR PNEUMONIA

A total of 582 persons who had been in recent intimate familial contact with cases of lobar pneumonia were studied. This represents an average of over three contacts per patient. In addition, nasopharyngeal cul-

TABLE 4—Prevalence of All Types of Pneumococci

Per cent positive	59.6	43

tures were made on 493 controls taken from the population at large. As far as possible, a representative distribution throughout the various seasons was obtained. The prevalence of pneumococci of all types in contacts and controls is given in table 4.

Seasonal influences played a definite rôle in the distribution of the pneumococci in both controls and contacts.

In table 5 is given the proportion of contacts and of controls that harbored pneumococci in the naso-

pharynx during the various seasons of the year. The striking features of this table are that:

1 The controls show a consistently lower percentage of positive cultures throughout the seasons.

2 Pneumococci are much less prevalent in both groups in the summer months than during the remainder of the year.

Seasonal variation of pneumococci in pneumococcus carriers (indicated by black dot) compared with pneumonia deaths (indicated by white dot) in Massachusetts in 1931-1932.

The percentage of positive cultures during each month for the combined groups of contacts and controls has been calculated in the accompanying chart. There is justification for combining the two groups, as subsequent discussion will bring out. This chart of monthly incidence shows a low incidence of pneumococci in the summer and a rapid increase in the early fall, followed by an apparent decline, with a second peak in the early spring. This is strikingly similar to the curve of incidence of acute diseases of the respiratory tract in the United States that has been demonstrated by Townsend and Sydenstricker⁷ and others.

PREVALENCE OF SPECIFIC TYPES OF PNEUMOCOCCI

A summary of the results which indicate the prevalence of the various types of pneumococci that were isolated from contacts and from controls, is given in

⁵ Heffron, Roderick. *New England J. Med.* 207: 13 (July 28) 1932.

⁶ Blake, F. G. *Ann. Int. Med.* 5: 673 (Dec.) 1931.

table 6 For the purpose of comparison, the distribution of the types of pneumococci that actually produced lobar pneumonia is inserted in the table

Several illuminating facts are brought out by table 6. There occurs a very general distribution of all types of pneumococci in both the contact and the control group. Type III is far the most prevalent, but there is no significant difference in its prevalence in the two

TABLE 6—*Distribution of Pneumococci in Cases of Pneumonia in Family Contacts and in a Control Group*

Type of Pneumococcus	Cases	Contacts	Controls	Cases per Cent	Contacts per Cent	Controls per Cent
I	48	11	1	27.7	3.2	0.5
II	34	18	3	19.6	2.2	1.4

Higher types	8	20	20	4.6	8.6	0.4
Negative	10	235	212			
Total	173	552	495			

groups (25 per cent in the contacts and 33 per cent in the controls). Types VI and XVIII are quite prevalent—from 10 to 15 per cent of the total in the contact group. These strains were equally prevalent in the control group. The most striking thing in the whole table is that all types from type III to type XIX inclusive show an almost exactly equal prevalence of each type in the controls and in the contacts. If one excludes types I and II, therefore, this table would seem to represent the normal distribution of pneumococci in the community during the year of 1932.

Only types I and II show any variation from the general rule. Type I is six times more prevalent in the contact group than in the control group, and type II is three times more prevalent. The great discrepancy that exists between the number of the contact group that harbors types I and II as compared with the control group is brought out if one considers only those persons that had positive cultures. In table 7 is tabulated the distribution of pneumococcus types among those actually infected, e g, 347 infected contacts and 212 infected controls.

TABLE 7—*Percentage of Infection with Pneumococci Among Three Hundred and Forty-Seven Infected Contacts and Two Hundred and Twelve Infected Controls*

Type of Pneumococci	Contacts		Controls	
	No. of Persons	Per Cent Infected	No. of Persons	Per Cent
Type I	11	3.1	1	0.4
Type II	18	5.2	3	1.4
Type III	87	25.0	67	31.6
All other types	231	66.5	141	66.4
Total	347		212	

These summaries (tables 5, 6 and 7) indicate that a group of persons in direct contact with cases of pneumonia harbor types I and II pneumococci more frequently than does the population at large. All other types of pneumococci are about as prevalent in the general community as in the control groups.

SEASONAL DISTRIBUTION OF VARIOUS TYPES OF PNEUMONIA

No conclusions can be drawn in regard to the seasonal distribution of each of the various types of pneumococci, since the numbers of some of the types are small. As I have already noted, the general trend of all types was a low incidence during the summer, with a sudden increase in October, followed by a slow decline until about February 1, then, a rapid increase, with the greatest prevalence in March, April and May and a rapid decline in late June. This seasonal variation occurred in both the contacts and the control groups. This general seasonal distribution also occurred in individual specific types wherever the number was sufficiently large to be significant. For example, types III, VI and XVIII were found throughout the year but were much more prevalent in the spring months. No one type was limited to one season, no strain appeared suddenly in the community and then disappeared, nor was there a significant difference in seasonal variation of specific types in the control and contact groups.

CORRELATION BETWEEN EXPOSURE TO PNEUMONIA DUE TO A SPECIFIC TYPE OF PNEUMOCOCCUS AND THE PREVALENCE OF THE HOMOLOGOUS STRAIN IN CONTACTS

A summary of the observations from the whole group of contacts is, of course, not so significant as a more specific analysis of the correlation between direct expo-

TABLE 8—*The Correlation Between Exposure to a Case of Pneumonia Due to a Specific Type of Pneumococcus and the Prevalence of the Homologous Type of Pneumococcus in the Nasopharynx of Contacts*

Type of Pneumonia	Total Persons Exposed	Correlated with Same Type	Per Cent of Correlation	Distribution of Pneumococci in the General Population	
				No. of Persons	Per Cent
I	186	10	5.4	1	0.9
II	126	14	11.1	3	0.1
III	61	13	21.3	67	13.6

All others	81	0		345	
Total	594			493	

sure to a patient with a given type of pneumococcus and the prevalence of the same type of pneumococcus in that patient's contacts. This analysis would tell just what proportion of individuals that have been directly and recently exposed to type I pneumonia harbor this specific strain in the nasopharynx. The results of an analysis of such correlations is given in table 8.

The percentage of correlation has been tabulated for each type of pneumococcus, and the distribution of that type in the control population has been given. Thus of 186 persons who were in direct contact with cases of pneumonia due to type I pneumococci, 10 harbored type I pneumococci, or 5.4 per cent, whereas only 0.2 per cent of the control group harbored this strain.

In analyzing table 8, it was noted that the contacts with cases of pneumonia due to pneumococci types VI, IX and XIV were so few in number that no conclusions could be drawn from the data. The prevalence of homologous strains of pneumococci in contacts with

cases of pneumonia due to types VII, XVIII and possibly also type III is not significantly greater than the general prevalence of these strains in the population at large

The data for two types of pneumococci in this table are significant, namely, types I and II

Type II was more than ten times more prevalent in contacts with type II pneumonia than in the population at large, and type I was twenty times more prevalent in persons exposed to this strain. A high correlation is noted also with types V and VIII, but the numbers of persons observed is much smaller than in the first two types. Though type I, type II and type III contacts are the only ones that occur in sufficient numbers to give significant data, it may be noted that there is some significance in the fact that all types in which any correlation occurred showed a higher prevalence of that type in the contacts than in the population at large

ECONOMIC STATUS

Our criteria for measuring economic status are admittedly faulty. We have made a rough classification of the data into three economic groups: poor, fair and good. A detailed analysis of these data showed no significant distribution of any single type of pneumococcus in any single economic group but rather a strikingly even distribution of all types of pneumococci through all groups.

An analysis of the correlation tables gave no evidence of a greater tendency for a person who has poor living conditions and who develops pneumonia to infect his contacts than those who live in a more fortunate economic situation.

OVERCROWDING

The same is true of overcrowding. Again the criteria are obviously at fault. So far as these data go, however, there was no evidence that an individual living under "overcrowded conditions" is more likely to harbor pneumococci than are other persons. Furthermore, contacts with a case of pneumonia in a family in which living conditions were "overcrowded" were not more likely to harbor the specific strain which had produced the pneumonia in a person of that family than were contacts who were exposed to that particular strain under more normal living conditions.

There were exceptions to this rule, notably with type V and type III, which will be reported in detail in subsequent studies.

THE RELATIONSHIP OF ACUTE RESPIRATORY INFECTIONS IN CONTACTS WITH CASES OF PNEUMONIA TO PREVALENCE OF PNEUMOCOCCI IN THE NASOPHARYNX

It has often been suggested that when an epidemic of colds affects a family, pneumococci become established in the nasopharynx in large numbers as secondary invaders. The development of pneumonia represents simply an extension of pneumococcal infection from the upper to the lower respiratory tract. Certainly, it is not an uncommon experience for a whole family to be affected by an epidemic of colds, followed by development of pneumonia in one member of the family only.

If the epidemiologic chain of events just outlined is the usual occurrence, one would anticipate that immediate contacts of a case of pneumonia in which the family had recently been affected by an epidemic of colds would tend to show a high prevalence of the

specific homologous types of pneumococcus in those contacts who had had recent colds.

An analysis of these data shows that pneumococci were no more prevalent in the contacts suffering with colds than in the population at large (table 9).

The data in table 9 indicate that the pneumococci, considered as a group of organisms, do not play an important role in the incidence of colds.

If one studies those specific types of pneumococcus in which a correlation occurred between the presence of the type in a case of pneumonia and the prevalence of the identical strain in contacts of that case, a different picture is revealed.

TABLE 9—Prevalence of Pneumococci in Pneumonia Contacts Who Had Recently Had Colds

	Cold at Present		Recent Cold (Within 4 Weeks)		No Colds	
	No. of Persons	Per Cent Positive	No. of Persons	Per Cent Positive	No. of Persons	Per Cent Positive
Contacts	104	50	51	64	423	60
Controls	79	51	60	48	350	40

The number of contacts who had a cold and who harbored the same strain of pneumococcus as was found in the corresponding case of pneumonia is small, but the data are significant.

Table 10 shows that nearly half of the contacts who harbored the same type of pneumococcus that was found in the case of pneumonia from their family had an "acute" cold. I have already noted that these correlations are limited to a small proportion of the strains of pneumonia (table 8). The data are too few to warrant any conclusion but suggest further study.

TABLE 10—Correlation of a Specific Strain of Pneumococcus in 'Contacts with Colds' with the Same Strain of Pneumococcus Isolated from the Pneumonia Patient

concerning the epidemiologic chain of events relating to the part played by the pneumococcus in the acute colds with subsequent pneumonia, and particularly to those cases of pneumonia which may be produced by pneumococcus strains I, II and III.

SUMMARY

The prevalence of various specific types of pneumococci has been determined in 582 family contacts of actual cases of lobar pneumonia and also in 493 controls. Cooper's classification of specific types of pneumococci—up to type XX—was used. Lobar pneumonia due to practically every type of pneumococcus was included in the series of 173 cases, though some of the higher types were infrequent.

The study was carried on through the four seasons of the year. We considered some of the environmental and other factors which may have an influence on contact infection, such as poor economic status of the family with accompanying overcrowded living conditions, seasonal variation, the age factor and the occurrence of acute colds in the family.

All the various types of pneumococci (excluding types I and II) were as prevalent in the general population as in the pneumonia contact group. Types III, VI and XVIII were encountered most frequently.

Types I and II, though responsible for more than half the cases of lobar pneumonia, were rarely encountered in the general population, but type II was three times more prevalent and type I six times more prevalent in the contact group than in the control group. This observation is in accord with the observations of other workers in this field.

Correlation tables of the prevalence of the specific homologous types of pneumococci in a case of lobar pneumonia and its family contacts indicate that the only strains that had a definite epidemiologic significance were types I and II. A fairly high correlation occurred with types V and VIII, but the numbers of persons exposed were small—thirty-two persons to type V and thirty-one persons to type VIII pneumonia.

A seasonal variation was observed in the prevalence of pneumococci in the nasopharynx of both contact and control groups, the highest incidence was noted in the early spring and the lowest during the late summer. This seasonal variation was not a peculiarity of any one type of pneumococcus.

There is no evidence from these data that poor economic conditions, with resultant overcrowding, influenced the distribution of pneumococci. Furthermore, the various specific strains were widely distributed through the various age groups.

Our evidence indicates that contacts having colds at the time of contact with a case of pneumonia did not harbor pneumococci more frequently than contacts with no colds. In some instances, however, an epidemic of acute colds in the family did seem to be a factor in the high prevalence of types I and II in contacts.

One question in relation to the epidemiology of type I and type II has not been answered by these studies, namely: Does a patient with lobar pneumonia due to type I or type II actually infect his family contacts or do these strains invade several members of a family—possibly following or coincident with a family epidemic of colds—with subsequent development of lobar pneumonia in one member of that family?

Either alternative might explain the relatively high prevalence of type I and type II pneumococci in family contacts of a case of pneumonia due to these types.

In an attempt to determine this point, we are conducting an intensive study of the families in which cases of type I and type II pneumonia occur.

CONCLUSIONS

1 In a study of over a thousand persons, type I and type II pneumococci were found to be much more prevalent in the nasopharynx in immediate family contacts of cases of lobar pneumonia due to the homologous type than in the population at large.

2 The higher types of pneumococci—types III to XIX, inclusive—were just as prevalent in the throat in the general population as in the family contacts of cases of pneumonia due to these specific types. The

types most frequently encountered were III, VI and XVIII.

3 The whole group of pneumococci was less prevalent in the late summer months than in the winter and early spring. No one type of pneumococcus showed any deviation from the general rule in seasonal distribution.

4 Poor economic conditions, with resultant overcrowding, did not, per se, increase the prevalence of any one specific type of pneumococci in contacts of pneumonia due to the homologous type.

5 The studies suggest that epidemics of family colds have some relationship to the prevalence of homologous types of pneumococci in contacts of lobar pneumonia due to type I and type II.

55 Van Dyke Street

TWO YEARS' STUDY OF LOBAR PNEUMONIA IN MASSACHUSETTS

RODERICK HEFFRON, M.D.

AND

GAYLORD W. ANDERSON, M.D.

BOSTON

Lobar pneumonia is a cause of death outranks all other infections, except tuberculosis. Standing in seventh or eighth place among the principal causes of death, it ranks second if one considers only persons in early adult life. In the United States Registration Area for the ten years 1920-1929 there were over one million deaths from all forms of pneumonia, 52 per cent of which were due to lobar pneumonia. Few if any diseases exact such a toll at the economic prime of life. It is therefore extremely fitting that in any consideration of public health some attention should be given to this disease. Yet almost without exception it has been completely neglected save for a passing remark of regret as to the futility of its control.

Quarantine seems to offer little hope of success, owing to the relative infrequency of secondary cases. A thoughtful health officer would hesitate to recommend the extension of such a procedure, which, as can be demonstrated for other diseases, has little more merit than the respect which properly comes with age. Control through immunization as that against diphtheria or smallpox is more logical, yet unfortunately it has not as yet been found practical or effective in dealing with lobar pneumonia. Future research should brighten this otherwise somewhat dark horizon.

There remains, then, but one method that offers any promise of success, namely, an attempt to lessen the toll of life taken by this as yet unpreventable disease. It has long been recognized as a proper function of public health that the governmental agency should offer to the public through the family physician certain special aids in the diagnosis and treatment of communicable disease. The bacteriologic laboratory aids the practitioner in arriving at a correct diagnosis, serums and vaccines produced and distributed by the city or state assist him in certain specific treatments or prophylaxes. It is therefore consistent that in a properly balanced public health program some attention should be given to the aid that can be extended the

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

practitioner in the diagnosis and treatment of lobar pneumonia

The diagnostic aid, viz., typing of sputum serves the useful purpose of guiding treatment, whether it is general medical or specific serum therapy, and has added much to epidemiologic knowledge concerning the pneumonias. Serums for type I and type II pneumococcus pneumonia have been available for some years but were not extensively utilized, owing to their relatively low potency. In 1924, Felton¹ evolved a method of concentrating these serums so that large doses of immune bodies might be administered in small volumes. This development opened a new field whereby the public health agency might aid the practitioner. In 1928 the Massachusetts Department of Public Health began to produce this concentrated type I and II antibody solution and distributed it for purposes of investigation to a few selected hospitals. When, in 1930, we took account of stock and attempted to determine whether or not the continued production and distribution of this serum was warranted, there was little or no uniformity of opinion as to the serum except that these hospitals which had used it viewed with dismay its withdrawal. Yet its withdrawal seemed almost inevitable, owing to the high cost of its production and the limited extent to which it had reached the patients most in need of it.

In the meantime, Cecil and Sutfitt,² Cecil and Plummer,³ Park, Bullowa and Rosenbluth⁴ and others had shown beyond reasonable doubt that treatment of type I pneumonia with this serum reduced the mortality approximately 50 per cent, especially if such treatment was instituted within the first four days of the disease. After that time, results were not nearly so marked. The few results that we had available indicated that the serum which the department was producing was of similar potency. One criticism of the work up to that time remained unanswered. This work had chiefly been carried on in a few large, well staffed and well equipped metropolitan hospitals and had been under the immediate supervision of clinicians who had more or less specialized in this disease. Could similar results be obtained with the use of the serum in smaller and less well equipped hospitals or, even more important, in the hands of the general practitioner of medicine? If a governmental agency was to continue to supply this serum free of charge, it should be made available for the treatment of the bulk of patients who might benefit from its use. Such patients were to be found not so much in a few large metropolitan hospitals (where they usually arrived too late to have the serum be of much use) as in the smaller hospitals and the home practice of the family physicians. Furthermore, more economical methods of serum production were desirable.

It was in an effort to find an answer to these problems that a study of lobar pneumonia in Massachusetts was undertaken early in 1931 by the state department of public health. The expenses of this study have been defrayed by the Commonwealth Fund of New

York City, since the questions to be answered had a bearing in all parts of the country, particularly in rural practice. Since the costs have been carried by a private foundation, it has been possible for us in the development of the study to carry on a certain arbitrary selection, which would have been questionable if the taxpayers' money had been spent. In the conduct of the study we have had the aid of an advisory committee⁶ composed of physicians of special experience in the problems to be met. The study has been conducted under three headings, only one of which, the clinical, can be discussed here. The other parts, the epidemiologic and the statistical, under the joint direction of Dr. Wilson G. Smilie of the Harvard School of Public Health and the department staff, and the laboratory study, under the direction of Dr. Benjamin White of the State Biological Laboratories, are being reported on elsewhere. Suffice it to say here that they may shed considerable new light on previous ideas as to the modes of spread of lobar pneumonia and may aid in the production of a better and more uniformly potent serum.

The clinical trial of the serum is being made by a group of collaborating physicians selected by the advisory committee. These were picked from certain areas each centering around a hospital, the areas in turn being so selected as to give representative samples of the state. There are at present fifteen areas with a total of sixty-three collaborating physicians. While some of these physicians had had special experience with lobar pneumonia, the majority had had no more experience than came from an extensive home and hospital practice. The observations, then, represent the results that might be expected at the hands of any group of intelligent physicians who have taken the pains to acquire a working knowledge of pneumococcus pneumonia serum therapy, which was provided through a one day course on pneumonia offered by the Harvard School of Post-Graduate Medical Education. This course was open to all physicians and has since been repeated twice.

The areas have been built around hospitals in order to provide laboratory service for the typing of pneumonia sputums. The technicians of these hospitals have received one week's training in sputum typing at the Boston City Hospital or in the State Bacteriological Laboratory to make them reasonably proficient in the various methods used and, above all, to assure uniform results. In order to obtain a check on the latter, cultures of all group IV pneumococci found by these hospital laboratories (which have facilities for only types I, II and III detection) have been forwarded to the state laboratory, where they are typed to thirty-two types, thanks to the courtesy of Miss Cooper of Dr. Park's laboratory, who has furnished diagnostic serums for these higher types. A preliminary report of our experiences with typing has already been published.⁷ These results have convinced us that the typing of sputum in the hospital laboratories has been remarkably uniform and accurate indicating that this is a procedure which can be undertaken in any reasonably equipped hospital laboratory employing a reasonably well trained and intelligent technician. wiede, Sabin and tube agglutination methods of typing have been used, with particular emphasis on the Sabin. In the state laboratory we have recently used, with considerable success and often with great saving of time, the Neufeld method of typing.⁸

Bivalent type I and II antipneumococcus serum, concentrated by Felton's methods, has been supplied to the collaborators for use in their home and hospital patients. It has been further provided that any of these collaborators would see a suspected case of lobar pneumonia with any physician in their area who might wish this serum for a patient. The cost of such consultations has been carried by the Commonwealth Fund if the patient was unable to afford the usual fee. A detailed report of all cases treated has been obtained from the collaborator.

In order to avoid delay in the administration of serum in early cases of lobar pneumonia it has been advised that treatment be begun as soon as the clinical

TABLE 1—Serum Treated Cases

Year	Number of Cases

diagnosis could be made but that in no instance should serum treatment be instituted after the fourth day of the disease. The serum, all given intravenously, was administered in doses of 5, 25 and 45 cc at intervals of two hours. Any further serum therapy has been conditioned by the results of type determination. If a type I or II pneumococcus was found, further serum might be given according to clinical indications. If any other type was found, further serum was withheld. However, since over half of all lobar pneumonias in young adults are due to either the type I or the type II pneumococcus, this treatment without preliminary typ-

II	61
III	21
Group IV	95
Streptococci and miscellaneous	36
Total	421

Total deaths, 79 crude fatality rate 18.7 per cent

ing has seemed justifiable to save time. In certain instances when the collaborator was called in consultation the administration of the serum has been left to the attending physician. Sensitivity to serum as detected by the ophthalmic test has been determined in every instance. A positive test or a history of asthma, hay fever, eczema, urticaria, angioneurotic edema or hypersensitiveness to horse serum or dander has been considered a contraindication for serum therapy.

To date, 421 cases of lobar pneumonia have been treated by sixty-three collaborators, as shown in tables 1 and 2.

A group of 349 cases of pneumococcus lobar pneumonia typed at the state laboratory but not treated

with serum has been collected. This group has been obtained in part by following up sputums sent to the laboratory for typing and in part by follow-up by the state district health officers of many cases of home and hospital treated lobar pneumonia within their several districts. The case fatality rate in this series may be seen in table 3, where it will be noted that home treated cases had a lower rate than hospital cases.

TABLE 3—Typed Cases of Pneumococcus Lobar Pneumonia (Due to All Types of Pneumococci) Not Serum Treated

	Total	Fatal Cases	Case Fatality Rate per Cent
Hospital cases	20*	4	20.0
Home cases	143	24	16.8
Total	349	71	20.3

Among the 349 untreated cases were 85 due to pneumococcus type I (about half were home and half were hospital cases). Of these 22 patients died giving a case fatality rate of 25.9 per cent. This control group is still small but it does afford some standard with which the treated cases may be compared.

In table 4 are shown the results of serum therapy in pneumococcus type I lobar pneumonia. We have included as treated cases only those patients who received more than 15 cc of serum and in whom such treatment was begun sometime during the first four

TABLE 4—Results of Serum Therapy Type I Pneumonia

	Cases	Fatal Cases	Case Fatality Rate per Cent	Average Age in Years	Average Total Dose per Patient
Treated	188	20	10.6	34.2	87.0
Untreated	85	22	25.9	34.3	

* Age distribution 11 to 81 years

days of illness. It will be noted that the case fatality rate of the treated group has been reduced to less than half that of the untreated group.

Among the 188 early serum treated type I cases blood cultures were done in 127 of which 35 or 27.5 per cent were positive. Usually pneumonias with a positive blood culture show a case fatality rate several times that of cases in which blood cultures are negative. The efficacy of the serum used is indicated by the results seen in table 5 in that patients with bacteremia

TABLE 5—Serum Treated Cases of Type I Pneumonia With and Without Positive Blood Cultures

	Total Cases	Fatal Cases	Case Fatality Rate per Cent
Culture positive	35	4	11.4
Culture negative	92	7	7.6

who were given serum early in the course of their disease did not show the high mortality rate usually seen in such bacteremic patients.

The results of similar early treatment of type II pneumonia, while encouraging, have not been as satisfactory as in type I cases. Of forty-eight type II patients treated with serum, twelve, or 25 per cent died. The number of cases in this group is too small to warrant definite conclusions.

COMMENT

The foregoing results, while representing merely the present state of a study which is far from being completed, are extremely encouraging in that they indicate that within limits it is possible to reduce materially the toll of deaths from certain types of pneumonia. Were serum therapy a measure so difficult in technique as to be feasible only in the hands of a selected few, we could hardly look forward to any general public health contribution in this field. Our results, as enumerated, indicating that under the conditions outlined the case fatality may be reduced over 50 per cent, lead us to hope that through far greater utilization of Felton's concentrated antibody solution a distinct contribution may be made toward reduction of the present high pneumonia death rate. There remains, however, the problem of developing a method for wider distribution of the serum consistent with the necessity of careful conservation of so expensive a product. At a later date we hope to be able to report on this.

SUMMARY

As a part of a study of lobar pneumonia in Massachusetts carried on during the past two years by the state department of public health with the financial assistance of the Commonwealth Fund, Felton's concentrated pneumococcus antibody solution has been used by physicians collaborating in the study to treat 421 cases of pneumonia. Among these were 188 cases of type I pneumonia that were treated with serum. This yielded a case fatality rate of 10.6 per cent as contrasted with a rate of 25.9 per cent of eighty-five untreated cases of the same type.

THE SIGNIFICANCE OF THE NEWLY
CLASSIFIED TYPES OF PNEUMO-
COCCI IN DISEASE

TYPES IV TO XX INCLUSIVE

W. D. SUTLIFF, MD
AND
MAXWELL FINLAND, MD
BOSTON

The classification of cases of pneumonia according to their bacterial etiology has proved of considerable value to our understanding of the disease. The majority of the cases are due to the pneumococcus, and a small minority are due to other pyogenic organisms. The division of the pneumococci into types has brought out the importance of types I, II and III and has made possible the development of specific therapeutic antiserums for types I and II.

A large number of strains that had not been serologically identified were formerly classified together for convenience as type or group IV¹. They were known to occur in a great variety of pneumonias and

other pneumococcal infections² but could also be recovered from the throats of about 50 per cent of normal persons on one examination, and from the throats of all on repeated examinations³. It remained for Cooper⁴ to isolate from the miscellaneous group IV twenty-nine serologically specific strains, identified by numbers from IV to XXXII, inclusive⁵.

Our object in this paper is to survey the incidence of these miscellaneous pneumococcus types in disease seen in a general hospital. It is anticipated that a comparison between the strains of organisms found in disease

TABLE 1—Number of Patients Examined

Organism Recovered	Total Cases		Pneumonia Cases	
	Number	Per Cent	Number	Per Cent
Pneumococci types I to XX	1,094	50	910	85

No significant organism	106		52	
Total	1,561		1,146	

and those found in the mouths of healthy individuals may lead to conclusions as to the saprophytic or pathogenic characteristics of each strain. Such a comparison is made possible by this symposium. The hope has also been entertained that the separation of cases of atypical and secondary pneumonia due to different bacteria into separate groups may bring some order into an otherwise confusing group of diseases.

CLINICAL MATERIAL AND METHODS

The bacteriologic and clinical material that forms the basis for this study was collected during the course of thirty-five months. The work was directed chiefly toward the identification of the pneumococcus type in cases of lobar pneumonia in the medical services of the hospital, but specimens were obtained from many secondary pneumonias and from many pneumococcal infections other than pneumonia throughout the hospital.

All specimens of sputum were examined by means of mouse inoculation. Blood cultures were made by inoculating 5 cc of blood into a flask containing 50 cc of nutrient broth. In many instances, pour plates with 1 cc of blood were made at the bedside. Other materials for culture were streaked on the surface of blood agar plates or inoculated into mice, or both.

The number of patients examined and the varieties of organisms isolated are indicated in table 1. In a total of 1,561 hospital cases, pneumococci were isolated and their type determined in 1,094 cases. Untyped

pneumococci were isolated in 170 cases. Other organisms, such as *Streptococcus haemolyticus*, the Friedlander bacillus and *Staphylococcus aureus*, were the principal invaders in 101 cases, making a total of 1,364 cases which form the data to be discussed. A pneumococcus was recovered from 94.3 per cent, or 996, of the 1,067 patients with pneumonia, and a specific serologic type was identified in 91.4 per cent, or 910 of the patients with pneumococci. In 307 cases autopsies were performed, from most of which further cultures were obtained directly from the lesions and in all of which an accurate anatomic diagnosis was possible.

In the present paper only a general survey of the large amount of material that has been collected is possible. Diseases due to the new pneumococcus types that were met in significant numbers or showed any unusual features deserve careful individual analysis, such as has been reported in another section of this meeting for pneumococci of types III and VIII.⁶ At this time, strains will be pointed out that will most likely repay further study. The following subjects will be discussed: the pathogenicity of the new pneumococcus strains, the reliability of sputum cultures, the incidence of the strains in patients with or without pneumonia, the tendency of each strain to produce lobar pneumonia or bronchopneumonia, to produce primary or secondary pneumonia, to produce death, or to produce purulent complications, the incidence of the strains at different age periods, and the relative incidence of organisms other than pneumococci. The peculiarities of types I, II and III will be mentioned in passing for comparison with the peculiarities of the new types.

PATHOGENICITY OF NEW PNEUMOCOCCUS STRAINS

Because the pneumococcus strains classed together in group IV have been shown to occur in the normal mouth as well as in disease, it has been necessary to

Chart 1—Lobar pneumonia due to type VIII pneumococcus ending in recovery

make clear the relationship of each strain to the disease, wherever possible, by means of multiple cultures from sputum, blood and lesions.

Two such cases may be cited. In the first (chart 1), a type VIII pneumococcus was recovered from the sputum of a patient on the second day after a typically

acute onset. A pneumococcus of the same specific strain was recovered from the blood stream on three different occasions. The clinical course was that of acute lobar pneumonia with a rather sudden termination and rapid convalescence. In the second case (chart 2), a type V pneumococcus was recovered from the sputum and the pleural fluid during life, and from the chest fluid and heart's blood at autopsy. The lesion was lobar in

Chart 2—Lobar pneumonia and empyema due to type V pneumococcus ending in death with postmortem cultures

type on histologic examination. Such cases have been seen in the presence of all but three of the seventeen new specific types covered in this study. In ninety-nine cases of pneumonia, such pneumococcus types have been obtained from the blood stream, lung or pleura.

RELIABILITY OF SPUTUM CULTURES

Owing to the wide distribution of group IV pneumococci among normal persons, it may be questioned by some whether the finding of such an organism in the sputum is evidence of its connection with pneumonia. By a comparison of the organism found in cultures of blood or cultures from infected lesions with that found in the sputum of 220 cases, an estimate has been made of the reliability of sputum examination for diagnosis of the organism at the site of the lesion. In 202 cases, the organisms recovered from blood or lesions were the same as those recovered from the sputum. Thirty-eight of these were distributed among eleven of the seventeen newer types. In only one instance, 0.5 per cent, did a direct contradiction between the two sources appear. A type V pneumococcus was found in the lung at the postmortem examination, while a type XVIII pneumococcus and a hemolytic streptococcus had been isolated from the sputum. In a total of eleven cases, 5 per cent pneumococci were not recovered from the sputum, although a pure culture of pneumococci of a specific type was later found from another source. In all such cases, only one specimen of sputum had been examined, and in the majority it had been described as unsatisfactory. In the six remaining cases pneumococci of more than one type or other pneumonia-producing organisms were found in the sputum in cases from which cultures from blood stream or lesions were also obtained. In four of these cases, two organisms were found in the sputum and in cultures of the blood or lung. Type I was associated with Friedlander's bacilli in one case, with type III in another and with type V

⁶ Finland, Maxwell and Sutliff, W. D. Pneumococcus Types III and VIII Infection to be published.

in another, type II was associated with type IV in the fourth case. In two instances, two different pneumococci were found in the sputum and only one in the lesion. In both cases type I was found in the lung, and type I with type XVIII in the sputum of one, and type I with type XIX in the sputum of the other. The hemolytic streptococcus and the staphylococcus were frequently present in typical pneumococcal infections at autopsy. In a few instances, however, they were obviously associated with the disease. They will be discussed later.

It is safe to assume, on the basis of these comparisons, that when one of these twenty types of pneumococci is found in the sputum of a patient who has pneumonia, by the methods used for making cultures in these cases, the same organism will also be found in the lung. When more than one serologic strain of pneumococcus is found in the sputum of a pneumonia patient by the methods used here, one may find a mixed infection in the lungs, but in any case one is quite sure to

—a total of 195 per cent. Two of these types, IX and XIV, were found almost entirely in patients with pneumonia. The proportion of cases of pneumonia or empyema in the whole group of the less frequent types IV, VI, and from IX to XX was 187 of 237, or 79 per cent.

Twelve per cent of the patients had no pneumonia but had either purulent infections, such as meningitis, otitis media, mastoiditis, osteomyelitis, salpingitis, peritonitis, septic abortion, abscess due to the pneumococcus, or no apparent pneumococcal infection. The proportion of patients with purulent infections was the same in the group of the six most common types as in the group of fourteen rarer types. The proportion of patients with no pneumococcal infection was lower among the six most frequent types than among the rarer types, 5 per cent as compared with 16 per cent among the latter. Types VI, X and XVIII stand out because they occur relatively more often in patients in whom no infection was diagnosed than in patients with

find one or the other of the organisms in the lesions or blood. If one of the two sputum pneumococci is type I, the examples show that type I is more likely to be found in the lung than the other organism.

INCIDENCE OF PNEUMOCOCCUS TYPES IN PATIENTS WITH AND WITHOUT PNEUMONIA

The incidence of twenty pneumococcus types is shown in table 2. Types I, II, III, V, VII and VIII were each recovered in fifty or more cases each making 5 per cent or more of the cases of pneumonia or empyema. From the standpoint of numbers, these types merit special consideration. They comprise together 78.4 per cent of patients from whom typed pneumococci were recovered and 81 per cent of the patients with pneumococcal pneumonia. They vary considerably in the frequency with which they occur in pneumonia or empyema. About 95 per cent of types I, II and V, about 90 per cent of type VIII, and about 80 per cent of types III and VII were recovered from patients who had either pneumonia or empyema. The remainder of the types numbered IX, XI and from IX to XX were each found in from 0.2 to 3.2 per cent of the cases

purulent infections. The total number of cases presenting purulent infection and the total number showing no pneumococcal infection from whom type III was obtained is by far the largest of any of the types.

LOBAR PNEUMONIA AND BRONCHOPNEUMONIA

It is of interest to note the associations of these pneumococci as etiologic factors in the classes of pneumonia that are generally recognized, namely, lobar pneumonia and bronchopneumonia. Such an attempt presents difficulties due chiefly to the fact that clinicians usually consider that sharp differentiation of the two processes is next to impossible. A division on the basis of post-mortem examinations is relatively simple and thus was used whenever possible. In the absence of postmortems, reliance was placed on roentgen and physical observations. The proportions of lobar pneumonia and bronchopneumonia diagnosed clinically agreed remarkably well with those determined at autopsy.

Chart 3 shows the number and percentage of lobar pneumonias and the number and percentage of bronchopneumonias that were found in patients from whom the six most frequent pneumococcus types were obtained,

and the number and average percentage of the remaining fourteen less frequent types. In chart 4, the distribution among the cases examined post mortem is presented. The generally higher percentage of bronchopneumonia among those coming to autopsy is probably the result of a higher death rate among the patients with bronchopneumonia. Type IX, in which fourteen cases among fifteen were found to be lobar pneumonia, is the only type other than types I and II that is asso-

cent, other organisms, 41 cases, 19 per cent. Of the typed pneumococci, the first ten types in order of frequency are III, VIII, XVIII, X, V, VII, XX, II, XI and XIV, making together 81.1 per cent of the whole.

The separation of the cases into lobar pneumonia and bronchopneumonia has brought out the progressively more frequent occurrence of bronchopneumonia in the six most frequent types according to their numerical order, and the relatively high incidence of bronchopneumonia in the average of the remaining fourteen types. Type IX is an exception to this, being found in lobar pneumonia in more than 90 per cent of the cases. The relative frequency of the pneumococcus types and other organisms differs markedly in lobar pneumonia and bronchopneumonia.

PRIMARY AND SECONDARY PNEUMONIA

In an etiologic classification of pneumonia, the conception of primary and secondary pneumonia is of

ciated with lobar pneumonia in more than 90 per cent of the cases. The other pneumococcus strains are associated with lobar pneumonia in the clinic (chart 3) in from 66 to 82 per cent of the cases, and in the necropsy room (chart 4) in from 25 to 76 per cent of the cases.

The relative incidence of all the organisms considered in this survey in the 839 cases of lobar pneumonia is as follows: typed pneumococci, 770 cases, 92 per cent, untyped pneumococci, 52 cases, 5 per cent, other organ-

Chart 4.—Percentage of lobar pneumonia and bronchopneumonia in cases examined postmortem due to pneumococci of types I, II, III, V, VII, VIII, and the sum of the remaining fourteen types. Black bar shows percentage of lobar pneumonia, white bar shows percentage of bronchopneumonia.

isms, 17 cases, 2 per cent. Of the typed pneumococci the first six types in order of frequency are I, II, III, VIII, V and VII, making altogether 84.1 per cent of the typed lobar pneumonia cases. The same organisms were found in 215 cases of bronchopneumonia in the following proportions: typed pneumococci, 140 cases, 65.1 per cent, untyped pneumococci, 34 cases, 16 per

cent, other organisms, 41 cases, 19 per cent. Of the typed pneumococci, the first ten types in order of frequency are III, VIII, XVIII, X, V, VII, XX, II, XI and XIV, making together 81.1 per cent of the whole. The separation of the cases into lobar pneumonia and bronchopneumonia has brought out the progressively more frequent occurrence of bronchopneumonia in the six most frequent types according to their numerical order, and the relatively high incidence of bronchopneumonia in the average of the remaining fourteen types. Type IX is an exception to this, being found in lobar pneumonia in more than 90 per cent of the cases. The relative frequency of the pneumococcus types and other organisms differs markedly in lobar pneumonia and bronchopneumonia.

obvious importance. There are certain situations in which patients already ill and in the hospital may develop either lobar pneumonia or bronchopneumonia. Since there is probably no difference in the exposure of such patients to contact with pneumococci and the exposure of other patients in the same hospital, it seems probable that the disease or procedures which they undergo either increase the ease of penetration of the organism to the lung or change the conditions in the lungs or body in such a way that the usual amount of organisms set up an infection more readily than usual. The types of primary illness that were considered are as follows: infectious diseases, surgical operations and obstetric procedures, and degenerative diseases. Chart 5 illustrates the proportions of lobar pneumonia and bronchopneumonia, which were primary and secondary. Lobar pneumonia due to the six most common pneumococcal types was secondary to the diseases just mentioned in a very small proportion of the cases, from 5 to 7 per cent of the total, with the exception of lobar pneumonia due to type III pneumococcus, in which 17 per cent of the cases were secondary. The average for the remaining fourteen types is 9.1 per cent. Bronchopneu-

monia, on the other hand, was secondary in the great majority of cases. Because the numbers in each type were comparatively small and the percentage incidence of secondary pneumonia in the individual types varied relatively little, only the average is shown in chart 5. Forty-seven cases were primary, and ninety-four cases, or 66.7 per cent, were secondary. No particular association between any individual primary disease and any pneumococcus type was noted.

DEATH RATES

From the point of view of the possible usefulness of the determination of the serologic type of the pneumococcus, no feature is more important than its prognostic value, which may be determined from the death rate in disease caused by the individual organism. The number of patients and the percentage of deaths are given in table 3 for each pneumococcus type in lobar pneumonia and bronchopneumonia separately and together. The mortality of type I and II lobar pneu-

71 to 55.5 per cent, types IX, XI and XIV apparently being less virulent, and types VI and XVIII more virulent than the average. For bronchopneumonia, the death rates of the different types are still more similar and uniformly high, averaging 63.2 per cent. It should be noted that both lobar pneumonia and bronchopneumonia caused by the organisms formerly classed as group IV are as serious as the pneumonias due to the more frequent types.

PURULENT COMPLICATIONS

The purulent complications occurring in pneumonia, as shown in table 4, were well distributed through the list of pneumococcus types, the incidence varying from none in some of the rarest types to as high as 28 per cent in type V. The latter type has a higher incidence of purulent complications, both empyema and others, than type I. Except for types in which the numbers

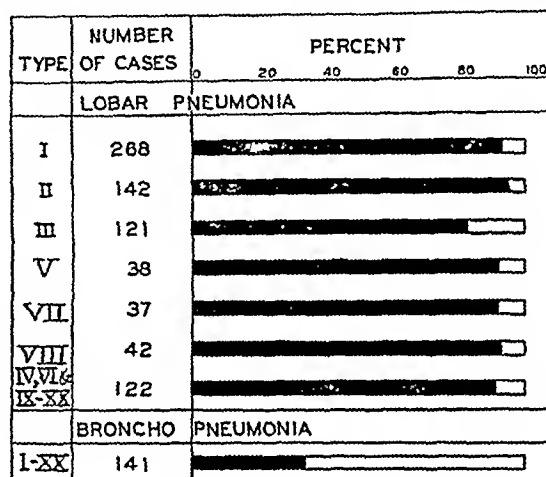

Chart 5—Percentage of primary and secondary cases among the lobar pneumonia cases and the bronchopneumonia cases. Black bar shows percentage of primary pneumonia cases; white bar shows percentage of secondary pneumonia cases.

are not significant, type I has the second highest incidence and is responsible for about 50 per cent of empyemas and other purulent complications.

TABLE 5—*Cases of Pneumonia from Which the Hemolytic Streptococcus, Staphylococcus Aureus and Friedlander Bacillus Were Recovered*

Organism	Pneumonia Cases		More Than One Organism Isolated						One Organism Isolated		
	Number	Per Cent of Total Pneumonia Cases	Number of Cases	Per Cent of Cases	Pneumococci Present			Number of Cases	Lobar Pneumonia Cases	Broncho pneumonia Cases	
					Number of Cases	Lobar Pneumonia Cases	Broncho pneumonia Cases				
											Number
Hemolytic streptococcus	77	7.9	20	26	20	14	6	47	10	37	
Staphylococcus aureus	32	3.0	28	88	19	12	7	4	1	3

Hemolytic streptococcus and Staphylococcus aureus from nine cases; Friedlander bacillus and hemolytic streptococcus from one case.

monia is modified by the inclusion of ninety-seven and forty-six specifically treated patients, respectively. Pneumonia produced by most of the different serologic varieties has similar death rates. For lobar pneumonia the average is 37.1 per cent. The variations that stand out and are based on a significant number of cases are those of type III and type VIII lobar pneumonia, the former having an unusually high death rate, the latter having a death rate lower than the average. Variations also occur among the less frequent types from

AGE DISTRIBUTION

Types I and II show a high incidence in early ages. Type III shows a high incidence in later age groups, as reported by others. The remaining pneumococcus types type VII, type VIII and the sum of the other fourteen present rather similar age curves, most of the cases occurring between the ages of 20 and 59 years.

INCIDENCE OF ORGANISMS OTHER THAN
PNEUMOCOCCI

In a relatively small proportion of the patients with pneumonia, organisms other than pneumococci were found in cultures from the blood or lesion. The incidence of each of these organisms, hemolytic streptococci, staphylococci and Friedlander bacilli, is given in table 5. The outstanding frequency of their association with pneumococci and with one another is noted (from 39 to 88 per cent of the cases). It seems probable that in many instances these organisms are secondary or accidental invaders in their relationship to pneumonia. This point of view is supported in the case of the hemolytic streptococcus and the staphylococcus by the observation that in the cases in which the pneumococcus and one of these organisms are associated the lesion is usually that of lobar pneumonia rather than of bronchopneumonia, whereas the lesion in the lungs when either hemolytic streptococci or staphylococci are found alone is generally patchy.

SUMMARY AND COMMENT

This general survey of the incidence of twenty serologically specific strains of pneumococci and of hemolytic streptococci, staphylococci and Friedlander bacilli in the pneumonia cases in a general hospital in an inter-epidemic period shows that each one of these organisms may cause the disease. The rare type-specific pneumococci numbered from IV to XX are consistently present in the sputum and lesions in certain cases of lobar pneumonia and bronchopneumonia. The presence of such pneumococcus strains in the sputum of patients with pneumonia is a reliable indication of their presence in the lung.

Exact etiologic diagnoses of pneumococcic pneumonia were made by the use of seventeen of the new typing serums, in a group of cases in which this has heretofore been impossible, amounting to 30 per cent of the total number of lobar pneumonia cases, and in 65.1 per cent of the relatively little understood and important group of bronchopneumonia and secondary pneumonia.

The order of frequency of the six most frequent pneumococcus types in pneumococcic lobar pneumonia is as follows: I, II, III, VIII, V and VII, making together 84.1 per cent of the cases, and the order of frequency of the ten most frequent types in pneumococcic bronchopneumonia is: III, VIII, XVIII, X, V, VII, XX, II, XI and XIV, making altogether 81.1 per cent of the cases. The six types most frequent in lobar pneumonia are also those most frequent in the whole series and have been given more attention than the others.

Certain individual characteristics of the pneumonias caused by the new pneumococcus types from IV to XX are brought out and compared with the better known types I, II and III. The three most frequent of the newer types are V, VII and VIII. Type V makes up 5 per cent of the total of pneumococcic pneumonias or empyemas and causes either pneumonia or empyema in 96 per cent of the cases in which it is found and leads to purulent complications in 28 per cent of the pneumonia cases. Type V is associated with lobar pneumonia rather than bronchopneumonia in only 81 per cent of the cases, in which respect it resembles most of the newer types. Its age distribution is quite irregular and without the usual preponderance in middle life. Type VII is associated with pneumonia or empyema in only 80 per cent of the cases but leads to

purulent complications in 11 per cent, a rather high proportion of these pneumonia cases. Type VIII is associated with pneumonia or empyema in 90 per cent of the cases in which it is isolated and has a low mortality in lobar pneumonia, 23.8 per cent, but, owing to an average bronchopneumonia mortality of 67 per cent, has a total mortality near the average.

The experience afforded by the bacteriologic classification of this series of pneumonia cases has indicated that the pneumonias due to different serologic strains of pneumococci and due to other organisms may be regarded as separate entities. By identifying such organisms in every case, the clinician may make accurate etiologic diagnoses and prognoses, the epidemiologist may unravel the factors affecting the organism and the patient leading to the development of atypical and secondary pneumonia, and the physician may apply the large amount of information about pneumococcus type specificity to the cure and protection from pneumococcal infections.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. SMILLIE, DR. HEFFRON AND
ANDERSON AND DR. SUTLIFF AND FINLAND

DR. H. A. REIMANN, Minneapolis. Drs. Sutliff and Finland have pointed out the desirability of regarding all cases of pneumonia from an etiologic point of view. This procedure is now inevitable. The terms lobar pneumonia and bronchopneumonia are becoming obsolete and will be superseded by terms indicating the causative organism. It is already possible to diagnose and classify by clinical and laboratory methods several distinct entities, for example types I, II and III pneumococcic pneumonia, streptococcic pneumonia and staphylococcic pneumonia. Other forms, although at present less well defined, are being actively investigated and no doubt will soon be clearly differentiated from the confused group heretofore regarded as bronchopneumonia. It is only by methods of etiologic classification that further progress can be made in the development of specific prophylaxis or therapy. The studies of Drs. Sutliff and Finland are of especial importance in regard to the pneumococcus types recently classified. It is no doubt bewildering at first to many, even to those actively interested in pneumonia, to learn that there are now thirty-two types, and number thirty-three has just been added by Silberstein. The question at once arises as to the practical application of the knowledge of these new types. At present obviously, it is technically impossible to prepare and have on hand thirty-three types of specific antiserum. The great value of the classification of pneumococcus types, as Dr. Sutliff stated, lies in furthering accurate diagnoses and prognoses and in regard to epidemiology. Gundel in Germany has shown that different types predominate in different localities which can be explained on the basis of contact infection. These studies are valuable additions to the knowledge gained in the various army camps during the influenza pandemic of 1918, namely, that the predominating form of pneumonia depends on the predominating organisms in a given locality. Although the recognition of the multiplicity of types of pneumococci would seem at first to be confusing and to be of purely academic interest, it will as a matter of fact, prove to be a simplification. It will become possible to recognize separate entities and to develop specific prophylaxis and therapy.

DR. WILLIAM H. PARK, New York. Those who have been in this pneumococcus work for some time realize the difficulties which Dr. Anderson and Dr. Heffron undertook when they tried to utilize in the smaller communities the knowledge obtained in our large hospitals. It meant that they must have laboratories with competent technicians, that they must have serum for at least some of the types that they must have clinicians available to meet the physicians in these smaller towns to aid them in their use of the serum. The work of Dr. Smillie and Drs. Sutliff and Finland is much in the line of what we have been doing in New York except that it is

even more extensive. One point I want to bring out which they didn't touch on is that in little children the comparative frequency of types is quite different from that in adults. This is true of both bronchopneumonia and lobar pneumonia. The percentage of bronchopneumonia under 2 years is much higher than that above 2 years. The streptococci are more frequently encountered in bronchopneumonia. While the type I pneumococcus is fairly abundant, type II is almost absent in children and type III is quite infrequent. There are five other types among the thirty or more separated equally important with type I, so that it is a much more complicated matter to treat children than adults, in whom types I and II cover about half the cases. Fortunately, type I serum is probably the best of the therapeutic serums, and type II is very useful. I question greatly the therapeutic value of type III serum. The types of pneumococci are only slightly allied, and for therapeutic purposes one must use a serum produced in a horse through the stimulus of the type of pneumococci producing the case of pneumonia to be treated. Unfortunately, the horse will make a good therapeutic serum for only two or, at most, three types of pneumococci, therefore it seems almost impossible at present to think of having serums for more than a few of the most frequent types because of the expense of obtaining these serums. At present types I and II are being made commercially and satisfactorily. As to the thirty types of pneumococci, there are really probably fifty or sixty types, but Miss Cooper has stopped tabulating the additional types. The point is that there are only seven or eight prevalent types and about twenty more slightly prevalent types, and the rest are so scattering that they are practically of no interest. I want to say that the thanks which have been given are not due me but to Miss Cooper. As to the use of pneumococcus vaccine, I think there is hope that physicians may be able to use a vaccine with advantage, because advances have recently been made in the preparation of vaccines and in methods of administration.

DR MAXWELL FINLAND, Boston. The clinician faced by a group of thirty-two different strains of pneumococci is doubtless appalled. The laboratory technician and the careful epidemiologist likewise feel overwhelmed at the idea of maintaining such a large set of serums and of agglutinating each pneumococcus with them all. In addition, the latter workers must also become acquainted with the special idiosyncrasies of each of these specific strains. This symposium and work along similar lines in Boston, New York and elsewhere in this country and abroad are doing much to simplify the current conception of the importance of the various types of pneumococci. From these studies it appears that only three or at most five or six of the newly classified types occur with any great frequency in disease. If these studies have done nothing more, they have shown the direction in which effort must be concentrated. I should like to add one word with respect to the etiologic relationship of the newly classified pneumococci to disease. During the past year Dr Alexander W. Winkler and I have studied the specific antibody response of patients with pneumonia associated with these types. Briefly, the immunity resulting from lobar pneumonia and, in many instances, from bronchopneumonia due to these types was found to be type specific in character. Agglutinins for the homologous type of pneumococcus were demonstrated about as frequently as in similar type I and II cases and agglutinins for heterologous types were very rare. We believe that these observations tend further to support the etiologic relationship of the newly classified types to pneumonia.

DR M. L. BARNES, Iowa City. I should like to ask Dr Smillie in regard to studies made on the normal cases as controls: how often does he find pure type cultures with these characteristics? How often did he find mixed types? He reported the homologous organism. I believe. How often did he find pure cases of homologous organisms may I ask?

DR WILSON G. SMILLIE, Boston. Individuals may have two or even three types of pneumococci in the nasopharynx but this is not a common occurrence. Usually an individual either a contact with a case of pneumonia or a person of the general population has only one strain in the nasopharynx. Dr Park mentioned the fact that there may be certain variations in different parts of the country or different parts of the world in relation to the incidence of these various types of pneumococci. This was shown interestingly in studies of isolated com-

munities in the South, in Alabama in Labrador in Spitzbergen and in the West Indies. These different communities have an entirely different picture so far as their specific types of pneumococci are concerned. Type III, however, is the most protean. It is feared most. It has the highest death rate of any of the types of pneumococci, and yet it is by far the most common type of pneumococcus one finds in general communities. One person out of every four in this assembly has the type III pneumococcus in the nasopharynx. Curious as that may be, it nevertheless is a fact. The death rate, when it produces pneumonia, is very high. It is a fatal disease of elderly people. The young people who have type III pneumonia are not likely to succumb.

RELIEF OF PELVIC PAIN BY SYMPATHETIC NEURECTOMY

REPORT OF SEVEN CASES IN WHICH THE SUPERIOR
HYPOGASTRIC PLEXUS (PRESACRAL NERVE)
WAS RESECTED

FREDERICK S. WETHERELL, M.D.
SYRACUSE, N. Y.

In this contribution I might well begin by paraphrasing the remarks of Dr Edward Archibald, who, before the seventeenth annual meeting of the National Tuberculosis Association in 1921, called attention to the backwardness of American surgeons in accepting thoracoplasty as an aid to the cure of pulmonary tuberculosis. He said "America is not generally supposed to be arriere, in matters surgical, nor is she, yet it is somewhat strange that in this country the treatment of certain types of pulmonary tuberculosis should have remained so far behind the standard set for some years back, in Europe." The substitution of "pelvic pain" for "pulmonary tuberculosis" expresses what I mean.

As far back as 1899¹ there were reports from European authors relative to the relief of various types of pelvic pain by means of sympathetic nerve surgery. A more recent contribution by Cotte² in 1925, however, is the basis on which the present operation is performed.

It is true that in the beginning many of the methods of approach and the structures attacked made the operation at times a formidable one. Experience and a better knowledge of the anatomy of the sympathetic nerve supply of the pelvic viscera have, however, made the operation as now practiced one which in competent hands should carry as low an operative mortality rate as any other elective pelvic operation. The same structures are attacked as in operations for the relief of motor dysfunctions of the lower intestinal tract, such as Hirschsprung's disease and the chronic rectal type of obstipation.³ I have been unable to find a mortality following this operation reported in the American literature. Fontaine and Herrmann⁴ report one death two days following operation. The autopsy disclosed only an edema of the brain, which would very likely in this case have followed any other pelvic operation.

From the Gynecological Department of St. Joseph Hospital.

The scope of this paper is not intended to cover the detailed anatomy and physiology relative to that portion of the sympathetic nervous system discussed. Only so much of these subjects as will give the reader a general idea is, therefore, included here.

GROSS ANATOMY OF THE SUPERIOR HYPOGASTRIC PLEXUS AND ITS CONNECTIONS

Coursing downward on either side of the anterior wall of the abdominal aorta may be seen two sympathetic nerves. They begin above at the origin of the superior mesenteric artery and are called intermesenteric nerves. At the level of the inferior mesenteric artery the left nerve gives off a plexus of nerves which follows the inferior mesenteric artery and its branches. Below the inferior mesenteric artery the two nerves unite to form the beginning of the superior hypogastric plexus (presacral nerve). This is rarely a single nerve, as a rule forming a true plexus. This plexus lies anterior to the bifurcation of the aorta and is separated from it by a thin layer of fascia. The main portion of this plexus usually lies in close relation to the left common iliac artery. At the upper level of the promontory of the sacrum the superior hypogastric plexus divides into two distinct nerves, called the inferior hypogastric plexus. Many variations of the plexus are encountered. In the main, it is a triangular mass and receives fibers from the inferior mesenteric plexus lying within the pelvic mesocolon at its left, and also from the lower ganglions of the lumbar sympathetic chain. Elaut⁵ has given the name "interiliac trigon" to the area in which the plexus is found. This trigon is at the level of the lower third of the fourth lumbar vertebra, the last intervertebral cartilaginous disk, and the fifth lumbar vertebra (the term "presacral" being therefore a misnomer). The apex of the triangle is at the bifurcation of the aorta and its sides are formed by the two common iliac arteries, the base being a line connecting the arteries at the upper level of the promontory of the sacrum.

The inferior hypogastric nerves, 2 or 3 inches in length, course along the internal iliac arteries and give branches to them which follow the various branches of the arteries. The nerve supply of the rectum and, in the main, to the ureters, is derived from the inferior hypogastrics. After these branches are given off, a mass of nerve fibers and ganglion cells is formed which is called the hypogastric ganglion. Visceral branches to the pelvic organs are derived from the medial surface of this mass. Five superior hypogastric plexuses removed from the patients whose histories follow show a general triangular outline and numerous communicating fibers.

PHYSIOLOGY

The sympathetic nervous system, as has so well been demonstrated in the surgery of this system in relation to vasoconstrictor disease, supplies the impulse of contraction to the arteries. The work of von Gaza⁶ points to the possibility that pain sense is conveyed by sympathetic nerve fibers. Pain in the viscera is dependent on other causative factors than is the pain from the body surface. The former results when there is abnormal distention, spasm or anemia.

The connections of ganglions of the sympathetic chain with the spinal centers explains the reference of pain to the surface. This pain is usually referred to definite segmental zones corresponding to the level at which the sympathetic fibers connect with the peripheral nerve fibers. The pains of gallbladder colic and ureteral colic, so well known to physicians, are classic examples. Relief of pain in the pelvis following resection of the superior hypogastric plexus indicates that pain impulses are conveyed to the central nervous system by way of these fibers, although the exact mechanism is still in question.

TYPES OF PAIN

Every physician in active practice has at times found himself at his wit's end to find therapeutic measures, excepting opiates, that would relieve pelvic pain. Many of the afflicted individuals have often been placed in the category of "disturbing neurasthenics." Most of these patients are seen in the beginning by the family physician, and his attention, as well as that of gynecologists and abdominal surgeons, should be called to the relief afforded by resection of the superior hypogastric plexus and to the types of pain that may be relieved.

Group A One of the severest types is the pain of metastatic involvement following carcinoma of the uterus.

Group B While not as severe, but nevertheless of a character that causes not only distress but also a varying amount of disability, is the pain that is present following pelvic operations. This group includes those cases in which the very pain for which the operation was originally performed is still present, and those in which the pathologic lesion found at the time of operation is often very slight in extent, consisting in the main of adhesions, or sclerotic ovaries that may or may not show cystic degeneration.

Group C The third type is the one occasioned by functional dysmenorrhea—unrelieved by any of the known therapeutic methods, not including the use of opiates, radiation or hysterectomy.

Irradiation and hysterectomy are such radical measures when applied to young women that an operation which conserves function and at the same time gives relief should readily be accepted by the medical profession as an addition to its therapeutic armamentarium, provided it is reasonably safe in its application. My experience has been limited to the three types mentioned.

Relief has also been reported in cystalgia, pruritus vulvae, vaginismus, and dyspareunia.

GROUP A

CASE 1—M. P., a housewife aged 29 married, entered the hospital, Oct. 12, 1932, because of prolonged and profuse vaginal bleeding of a year's duration. A year before her admission she noticed that she was flowing longer at each period and that there was an increasing dysmenorrhea. For the past few months she had bled from twenty to twenty-five days every month and this flow was accompanied by steady pain in the lower part of the abdomen and in the umbilical and both iliac regions. A section from the cervix showed epidermoid carcinoma. She was in severe pain constantly, yet pelvic examination showed the uterus freely movable and there was no indication of extension of the malignant condition. The growth seemed to be confined to the posterior wall of the cervix. Her temperature ranged from normal to between 100.4 and 102 F. There was great tenderness on bimanual examination and the possibility of a subacute pelvic inflammatory disease was considered. Her sedimentation time, taken on five different occasions from October 12 until November 15 ranged

⁵ Flaut I. The Surgical Anatomy of the So Called Pre sacral Nerve. *Gynec. & Obst.* 55: 581 (Nov.) 1932.

from ten to forty minutes. Her pain became so severe that she required several doses of one-sixth grain (001 Gm.) of morphine every twenty-four hours, and she had a very poor appetite, eating but little.

It was decided to explore the pelvis, which was done, November 21, with the idea of removing chronically infected fallopian tubes, if found, so that radiation therapy might be begun. The tubes were found to be slightly thickened, with thin adhesions to the broad ligament, but they did not have the appearance of having been the site of any recent inflammatory reaction. They were not removed because of the feeling that it would not be well to do so in the presence of a malignant condition. Our judgment proved correct in that there was no reaction following irradiation. The hypogastric plexus was dissected free and removed. At the end of the abdominal operation, radium was inserted in the cervix. A second treatment with radium was given, December 7, and at this time the patient was still free from pain. Three days after the operation she stated that she was entirely free from her pain, and she had not required an opiate since the first day after the operation, was hungry and eating well. She was still comfortable in February, 1933.

CASE 2—G. T., a housewife, aged 30, married, admitted to the hospital, May 22, 1933, complained of terrific pain in the pelvis and inner side of the upper left thigh. She had been in the hospital on two previous occasions during the past two years for the treatment by radiation of carcinoma of the cervix. Examination on admission disclosed a grade 4 carcinoma, the uterus being fixed and with definite extension into the parametrial tissues. The pain was without a doubt due to the extensive metastatic involvement. She had been getting one-sixth grain of morphine hypodermically every three or four hours, despite which she often screamed with pain. A superior hypogastric resection was done, May 29.

The patient required one dose of morphine the first day after the operation. On the second day after the operation she began to complain of the pain in her thigh, saying that the pelvic pain was entirely relieved but the pain in the thigh was still present and as severe as before. A small dose of codeine relieved the pain in the thigh, which was only spasmodic on the tenth postoperative day.

Case 1 is an example of severe pelvic pain in an early carcinoma of the cervix. The growth was limited to the posterior wall and the explanation may be that a secondary inflammatory reaction in the uterosacral ligaments, which are very richly supplied by sympathetic nerves, accounted for the pain. It has been suggested that, since many grade 3 and grade 4 carcinomas eventually cause severe pain, it might be well to explore the pelvis and do a "prophylactic resection" of the superior hypogastric plexus. There can be no objection to resection in carcinomas of grades 1 and 2, particularly if there is pain present. Such a routine would give the operator an excellent insight into pathologic conditions existing in the pelvis in conjunction with carcinoma and might be an aid in determining the technic of future irradiation in a given case.

In case 2 the mesentery of the sigmoid was displaced to the right in the manner described by Elaut,² which made the resection difficult and precluded the possibility of doing either a periaarterial sympathectomy of the common and external iliac arteries or a ganglionectomy of the lower left lumbar ganglions. It is for that reason that this patient still has pain on the inner side of the thigh. As soon as the patient's condition permits, a left lumbar ganglionectomy will be performed.

GROUP B

CASE 3—M. K., a housewife aged 42, married, admitted to the hospital Aug. 25, 1932, complained of sharp pain in the lower part of the abdomen and pelvis and in the sacral region, the pain being practically constant. She also complained of frequency of urination (every ten to fifteen minutes). The

latter she had noticed for one year, although the present frequency had been present for only two months. There was no burning on urination. Urologic examination disclosed nothing to account for this frequency. There was no sugar in the urine. The blood sugar was 131 mg. She had had two operations for ectopic pregnancy. Pelvic examination disclosed a moderately enlarged, nodular uterus with some evidence of the presence of adhesions.

Examination of the lumbosacral spine revealed no lesions that could account for the back pain. She was operated on, August 30. The uterus, about the size of a small grapefruit, contained numerous fibroids and was removed with the left ovary. The right ovary, which appeared normal, was left in. Her postoperative course was uneventful. She was seen in the follow-up clinic at monthly intervals until December 20, and the last report from her is dated May 31, 1933. She has had no pain and has had regular bowel movements without the use of cathartics, which were taken regularly before the operation. The urinary frequency gradually lessened until Dec. 20, 1932, when there was a three and one-half to four hour frequency, but her last report states that she is again having a one-half hour frequency.

CASE 4—K. M., a housewife, aged 25, entered St. Joseph Hospital, Oct. 3, 1932. Her chief complaint was a severe, constant, aching pain in the right lower iliac region with some pain also present in the left iliac region, which, however, was not quite as severe as that on the right side. Pelvic examination disclosed a uterus about the size of a two months pregnancy, and generalized pelvic tenderness. The Aschheim-Zondek test was positive. She had one child, aged 5 years. Since the birth of this child she had two miscarriages, one three and one-half years before admission, which occurred at six and one-half months, and one two and one-half years before, which occurred at six and one-half months, six months before, she aborted at six weeks. Her last period was two months before admission. At that time she went to bed for four days because of pain and cramps. This was her last menstruation up to the time of her admission to the hospital.

She had been in another institution before her admittance to St. Joseph Hospital, having gone there because of the severity of the pelvic pain. Nothing was done about it during her stay there except to give her anodynes, which gave her very little relief. It was quite apparent that the woman was having severe pain and this pain was not typical of any definite pathologic condition. There was some tenderness over the appendix, but the pain of which she complained was all below this point.

All the usual medical means for the relief of her pain were tried for a week, but nothing short of opiates gave her any relief. It was then decided to do an exploratory operation with the idea of removing any pathologic conditions which might be found.

The appendix seemed to be somewhat congested and it was removed. The uterus was about the size of a two months pregnancy. The superior hypogastric plexus was resected. The appendix was removed as a routine, yet the pathologic report states that there was "chronic and some acute appendicitis." She left the hospital October 23, twelve days after the operation and was entirely free from the pain for the relief of which she had entered the hospital. Five months later she was still free from the pain, and there had been no effect on the pregnancy.

CASE 5—A. D., a woman aged 32, divorced, admitted to the hospital Aug. 26, 1932, complained of generalized pelvic pain. She had had three abdominal and pelvic operations for the relief of pain over a period of six years, yet she still suffered from the same pain. She had recently been discharged from another hospital with the diagnosis of neurasthenia. Pelvic examination disclosed generalized tenderness. The director of the local Veterans Bureau stated that the woman had cost them many hundreds of dollars and that they were anxious to have something done that would rid her of her pain. They doubted very much, however, because of her repeated visits to hospitals that anything could be done for her and were rather unwilling to shoulder any more financial burden in her case. On the off chance, however, that a superior hypogastric

resection might relieve her pain, this operation was performed, August 30, by my associate, Dr. Floyd R. Parker. The only pathologic conditions discoverable were a few adhesions and a sclerotic, cystic ovary. The ovary was removed. One ovary remained. In December, she reported complete relief.

CASE 6—A. L., a housewife, aged 23, married, admitted to the hospital, Sept. 1, 1932, complained of pain in the lower right side of the abdomen. This pain had been very severe for one week before her admission. She had had some pain in the right groin for six months, the pain radiating upward toward the kidney and downward into the right thigh. She had no urinary symptoms at any time. There was no pain on the left side. Urologic examination disclosed no pathologic condition. In November, 1929, her right tube, ovary and appendix had been removed. On pelvic examination, there was tenderness in the right adnexal region. There was some tenderness posterior to the uterus. The cervix was hard and somewhat hypertrophied, and both lips were somewhat eroded. The tenderness on abdominal palpation was mainly below the costovertebral angle and around to the right iliac region. This pain had been reproduced by right ureteral catheterization.

She was operated on, Sept. 17, 1932. Three light adhesions of the omentum to the anterior abdominal wall were noted. The sigmoid and the terminal ileum were lightly adherent to the posterior surfaces of the uterus and broad ligaments. The right tube and appendix were absent. The left tube and ovary were adherent to each other and to the sigmoid colon. When separation of the left tubo-ovarian mass was begun a chocolate colored fluid appeared. What looked like a small mass of endometrial material was squeezed from the ovary, leaving an area about 15 cm. in diameter, the base of which contained a yellow area, probably corpus luteum. This diagnosis was confirmed by the pathologic examination. The adhesions were freed. The left tube was removed with its interstitial portion and the ovary was suspended to the left cornu of the uterus. A superior hypogastric resection was done. The follow-up notes on this patient show that she has been entirely free from pain since her operation. During April and May of 1933 she flowed excessively at the time of her periods and passed many clots. She went to the hospital, May 26, for a diagnostic curettage. The curettings showed chronic hyperplastic endometritis. Endocrine therapy is undoubtedly indicated.

There is no gross pathologic lesion to account for the pain in case 3. If a fibroid uterus or light adhesions *per se* were the causative factors, all women with such conditions present in the pelvis would suffer pain. This is known not to be so. Another factor not yet disclosed may be at work. It may be either a pelvic sympathetic supply, which is peculiarly susceptible to insult by extrinsic causes, or some lesion in the ganglions or nerves themselves.

In case 4 it cannot be conceived that the pain of which the woman complained was entirely due to the pathologic condition of the appendix. Resection of the plexus has no notable effect on pregnancy or parturition, according to reliable reports.

Patient 5 was relieved of her pain, yet nothing was done except the nerve resection and the removal of one ovary. She was seen at monthly intervals for four months and had not had a return of the distress.

In case 6 the pathologic condition that was present was on the left side of the pelvis, yet the pain of which the patient complained was on the right side and was undoubtedly of ureteral origin. As has been stated before, the main sympathetic supply of the ureters is in relation to the superior hypogastric plexus, and it may be presumed that for this reason she is now free from pain. The fact that the patient has begun to flow excessively does not coincide with the observations of Fontaine and Herrmann.⁴ The pathologic report of hypertrophic endometritis seems to indicate that she is in need of endocrine therapy.

GROUP C

CASE 7—P. L., a woman, aged 26, a nurse, married, complained chiefly of severe dysmenorrhea of a disabling character. She had had dysmenorrhea ever since she began to menstruate at the age of 14. Her periods had always been scanty, and for the past two years the dysmenorrhea had been of such a character that she was obliged to spend most of her time in bed during each period. These periods of disability were being so prolonged that she was unable to work at her profession, in fact, during and following her last menstruation she had been in bed nearly three weeks. She was very obese, being about 80 pounds (36 Kg.) over average weight. She had had all the usual medical treatment for the relief of dysmenorrhea and had come to the point at which operations had to be administered by her physician during her disability period.

She was operated on, Oct. 2, 1932. The uterus was normal in size but both ovaries were markedly sclerotic. The left one was incised and was found to be of the consistency and appearance of a piece of very hard, white cheese. The left ovary was removed. The greater part of the right ovary was removed, a piece about 1 inch long, 1/2 inch wide, and 1/4 inch thick being left. The superior hypogastric plexus was then dissected out and excised. Five days after the operation the patient noticed moisture in the bed and found that she was menstruating, having had no premonitory symptoms. One month later she again began to menstruate without warning. She noted that the amount of flow was as much during these two periods as she had ordinarily had in a year. Recent conversation with the patient discloses the fact that she is menstruating regularly every month and that she is entirely free from dysmenorrhea.

Case 7 is a typical example of a severe dysmenorrhea, showing that one may conserve ovarian function and yet have definite relief of pain. Attention is called to the economic feature in this case and in case 6.

OPERATION

Briefly, operation is done as follows. A midline incision is made extending from the symphysis pubis to or, better still, slightly above and to the left of the umbilicus. (An extreme Trendelenburg position aids greatly.) The pelvis is explored and any gross pathologic conditions are treated in the usual manner. The sigmoid and the small intestine are packed off. The bifurcation of the aorta is palpated, and the parietal peritoneum is picked up just below it and nicked with scissors. The area described under "anatomy" is laid bare. Then, with the aid of blunt right angled hooks, the fibers of the plexus are picked up and bluntly dissected with a small moist cotton ball on forceps.

This dissection is carried upward to the beginning of the plexus and downward to the beginning of the inferior hypogastric nerves. The bundle of nerve fibers is resected at these points. All communicating fibers are cut during the resection and the posterior parietal peritoneum is closed over the area.

In a certain percentage of cases, difficulty may be encountered because of the implantation of the meso-sigmoid to the right, but a small nick in the right leaf, which is then enlarged by careful tearing rather than cutting, results in a good exposure of the interiliac trigon.

SUMMARY

1 The relief of pelvic pain and of functional dysmenorrhea followed the operation in seven cases of resection of the superior hypogastric plexus (presacral nerve), as practiced for several years by various European surgeons.

2 The results, as reported in the literature and from personal experience, indicate that there is a definite value in the procedure, in certain cases the procedure allows the conservation of female reproductive organs which have heretofore been sacrificed.

3 Complete examination of the patient from all standpoints and all known methods of relief short of the use of opiates, radiation and hysterectomy should be carried out before resort is made to sympathetic neurectomy

CONCLUSION

The experience of American surgeons who have performed the operation of superior hypogastric neurectomy for other than painful conditions of the pelvis bespeaks its safety. Reports emanating from European clinics, along with personal experience, forces me to concur in the statement of Fontaine and Herrmann* that it is "a safe, simple, and efficacious way of interrupting these pathways in the treatment of the functional type of dysmenorrhea as well as a method of relieving other forms of severe pelvic pain."

Medical Arts Building

ABSTRACT OF DISCUSSION

DR J P GREENHILL, Chicago. All gynecologists come in contact with women who suffer excruciating pain as the result of grade 3 and grade 4 carcinoma. Up to the present time most of us have been giving these women large doses of opium derivatives. There are, however, two surgical procedures which can give these women immediate and long-lasting relief. One known as chordotomy, requires a knowledge of neurologic surgery. The operation consists in the removal of the laminae of the second, third, fourth and fifth thoracic spines and an incision in the anterolateral column, which if it is not exactly placed may not only fail to relieve the pain but may result in permanent paralysis of the legs. The second operation, sympathectomy, is a very simple operation and can be performed by any one trained in abdominal surgery. The indication for this operation is severe pain in the lower abdomen in the back, and down the legs. Not all patients with inoperable carcinoma will be relieved of their pain by this procedure. If a woman has distant metastases, if she has pain due to involved glands pressing on the obturator nerve, or if there is pressure on the sacral nerves this operation will not give the desired relief. Unfortunately, there is no way of detecting these three contraindications. However, since these three sources of pain are not common most women who suffer from inoperable carcinoma of the cervix should be subjected to this operation which entails practically no risk. Two months ago Dr Herbert Schmitz and I reported a series of thirteen cases before the Chicago Gynecologic Society. All these patients had inoperable carcinoma of the cervix. I have performed ten of these sympathectomies for inoperable carcinoma of the cervix, two for bladder carcinoma and one for dysmenorrhea. I might say that in all thirteen cases the results were spectacular, all the patients had complete and instant relief from their pain. One word of explanation is necessary for the patient with dysmenorrhea. In spite of the glowing reports which appeared in the French literature I have always felt that a laparotomy for dysmenorrhea is heroic treatment. However, one patient absolutely insisted on the operation when told about it. She had dysmenorrhea for fifteen years and spent from three to eight days in bed every single month. I performed the operation and she had a menstrual period in the hospital without any pain for the first time in fifteen years. Of course part of this result may have been psychic. Furthermore the patient has had only one period since the operation, so I cannot tell how permanent the results will be.

DR CHARLES H FRAZIER, Philadelphia. I am somewhat of an intruder in this section but I venture to speak because I am interested in the relief of intractable pain from carcinoma of the pelvis. In my clinic since 1914 we have performed the so-called Spiller operation, i.e. section of the anterolateral columns of the cord for the relief of pain and more recently we have tried the effect of the operation on the sympathetic system. Dr Wetherell gave a rather pathetic picture of chordotomy. The exposure doesn't have to be as extensive as he imagined and by the technic now practiced, complications

may be avoided. How is one going to differentiate between cases in which the presacral nerve should be resected and those in which a chordotomy should be done? From an experience covering almost twenty years I can assure the patient that chordotomy will give relief. No one will dispute that a laminectomy as preliminary to a chordotomy is a little more formidable operation than a simple laparotomy as preliminary to a resection of the presacral nerve. Can one determine before hand which of the two radically different operations is indicated? About two weeks ago I operated on a patient of Dr Floyd Keene's whose pain seemed to be confined altogether to the pelvic viscera. Since the afferent or sensory supply from the pelvic viscera passes through the presacral sympathetic nerve, the resection of this nerve in this particular case seemed clearly indicated. But when this terrific pain is referred, as it often is, to the back or the extremities, is it worthwhile even to consider a resection of the presacral nerve? All these patients have been suffering intolerable pain, most of them are more or less addicted to morphine. But I think it will be agreed that morphine is not the answer to pain in these cases. To patients who at the most may have only six months' expectation of life, one should be able in proposing any operation to guarantee relief from pain. I should like to know how Dr Wetherell differentiates between the groups which should be operated on by his method and the groups which should be operated on by chordotomy. I should like to ask him whether, as after chordotomy, the results of sympathectomy are permanent, and one more question from his own experience, has he found that a periarterial sympathectomy of the common and internal iliac veins, as proposed by Leriche, gives relief of pains referred to the back and the extremities? In the large majority of the patients on whom I have happened to operate, those are the pains of which the patient complains most.

DR FREDERICK S WETHERELL, Syracuse, N Y. This is the "creeping age" in the matter of sympathectomy for relief of pain. As Dr Frazier has intimated, chordotomy has a definite place as a procedure for the relief of pain. The important point about chordotomy is that it must be done by an expert neurologic surgeon and, for that reason, many patients will be without relief unless they are transferred to centers where such expert service is available. Any competent surgeon, with special study, can perfect himself in sympathetic nerve surgery, and thus men throughout the country will be available for such work, provided, of course, it is found as time goes on that relief can be given by means of sympathectomy. Dr Frazier asks as to the type of pain that may be relieved by sympathectomy and the type which may require chordotomy. Experience has shown that the cases in which the Head zones map out an area which indicates that the pelvic viscera alone are affected constitute the type in which relief might be expected by resection of the superior hypogastric plexus. When the pain is extensive and extends above the proper zones, the case would probably be one for chordotomy, although it must be remembered that strong impulses may jump several segments and in that way disturb one's observations. I feel that a superior hypogastric plexus resection might well be tried before chordotomy is resorted to, for the pain may be so modified that further work might not be necessary. In answer to the question regarding Leriche's operation of periarterial sympathectomy of the common iliac artery and external iliac artery, I feel the same. I suspect as Dr Frazier does that is, that since the sympathetic distribution to the extremities is a segmental one, much may not be gained by this type of sympathectomy. However if the pain in the lower extremities is close to the inguinal ligament it is possible that a periarterial sympathectomy may be of some value. Care must be taken in selecting cases for sympathetic neurectomy and I doubt whether any one man at this time will have a large series of cases to report especially as regards the classifications other than advanced carcinoma. I would further urge those who are contemplating doing this type of surgery that they first familiarize themselves with the structures attacked by study on the cadaver. It would be most unfortunate to have this work receive a setback at this time because some surgeon failed to pick up and resect the proper structures or did not resect a sufficient amount of nerve tissue. This I know has happened not only in pelvic but in other types of sympathectomies and it is most unfortunate.

INDICATIONS FOR ENTEROSTOMY

THOMAS G ORR, MD

KANSAS CITY, KAN

Enterostomy as a therapeutic measure in intestinal obstructive lesions and in the distention of peritonitis has been quite generally accepted by the majority of surgeons. There has not, however, been a universal agreement concerning its indications or complete accord in the interpretation of its results. The general impression is gained that the operation is frequently done as a last resort when little or no result may be logically expected. It must also be recognized that many patients, apparently treated successfully by enterostomy, might recover without drainage of the bowel if properly treated by modern supportive methods.

The logical use of enterostomy as a drainage operation involves some understanding of the pathologic changes and perverted function present in diseases associated with distention of the bowel. It has been quite conclusively shown that a bowel which retains its normal muscle tone and peristaltic activity does not absorb substances it should not absorb. If, however, blood supply to the bowel wall is damaged, the toxic content may reach the blood stream and produce symptoms.¹ After the bowel is paralyzed from overdistention, drainage of more than a short segment cannot be anticipated. If peristalsis is still active, drainage of the content of the small bowel may be expected, provided the enterostomy tube is functioning. Enterostomy is indicated to remove from the bowel its content of gas and liquid, not primarily to prevent absorption of toxic material but to prevent overdistention and paralysis.

Statistical studies have generally not shown that enterostomy decreases the mortality of intestinal obstruction and peritonitis.² Such statistics are of doubtful value, since they do not sufficiently consider that many enterostomies have been done as last resort operations when hope of adequate bowel drainage could not reasonably be entertained. It would seem that rather too much has been expected of enterostomy and not sufficient attention given to its indications and limitations.

The indications for intestinal drainage have grown less in recent years, since the chemical changes and disturbed physiology of the body, incident to obstructive lesions of the stomach and small intestine, are better understood. By maintaining the chemical and water balance, the tone of the intestine is in some degree improved. The use of morphine in adequate doses also increases the tone and rhythmic activity of the intestine. By these methods, overdistention is better controlled than formerly, thereby decreasing the indications for enterostomy.

High jejunostomy has received more than its share of commendation as a means of relieving distention of the upper part of the small bowel. It is very doubtful whether as much can be accomplished with a high jejunostomy as with an indwelling duodenal or stomach

tube. With the latter, the stomach and the upper portion of the intestine may be frequently aspirated of its contents or may be continuously kept empty by light suction.³

A summary of indications for enterostomy may be listed as follows:

- 1 For acute intestinal obstruction as a preliminary operation
- 2 As an adjunct to exploration and release of simple intestinal obstruction
- 3 As an adjunct to resection of the bowel for volvulus or other strangulation
- 4 After operative relief of intussusception
- 5 For obstruction due to lower abdominal peritonitis
- 6 For postoperative obstruction

Undoubtedly, complete surgical relief of a mechanical intestinal obstruction is always desirable when the condition of the patient will permit such an operation without too much danger to life. Many times the patient is too ill for an extensive procedure and in such cases enterostomy is helpful as a part of the treatment preliminary to operative relief of the actual occlusion. Exploration of a complete obstruction should not be delayed following enterostomy longer than is absolutely necessary to control the distention and restore the chemical and water balance. I have had two patients who developed necrosis and perforation at the site of the obstruction within two days following successful ileostomy. Both patients died of a diffuse peritonitis. Following an operation for relief of an obstruction or resection of a strangulated intestine, enterostomy just proximal to the site of obstruction is indicated to aid in a rapid relief of distention and to protect the damaged intestine until function is restored. After reduction or resection of an intussusception, drainage of the small bowel is also an operation of choice.

Obstructions following operations on the lower part of the abdomen or secondary to pelvic peritonitis are usually best treated by enterostomy. It is frequently quite difficult to determine whether or not a true mechanical occlusion exists. Loops of intestine may be only temporarily thrown out of function by adhesions or infection. An enterostomy will often relieve the distention until the function of the intestine has been spontaneously restored, and no further operation will then be indicated. An exploration to relieve such an obstruction is usually accompanied by grave danger. If peristalsis is still active, as shown by inspection and auscultation, enterostomy is successful in a high percentage of cases.

If a generalizing peritonitis has developed, it is doubtful whether an enterostomy is of much value. Animal experiments have shown that life is not prolonged by enterostomy in the treatment of diffuse peritonitis.⁴ In a series of eighteen patients, treated by enterostomy for peritonitis developing as a complication of intussusception, carcinoma of the colon, appendicitis, abortion, congenital anomaly, pelvic operation, ulcerative colitis and intestinal obstruction with perforation, all but one died. That somewhat ill defined group spoken of as paralytic ileus is usually not successfully treated by enterostomy. If an enterostomy is successful, the condition is not true paralytic ileus.

If proper function of an enterostomy tube is to be expected, it must be given constant attention. Frequent

From the University of Kansas School of Medicine.

injections of salt solution are indicated to maintain its patency. In selected cases, water and salt may be given through the tube to test the recovery of the bowel or to stimulate peristalsis.

The enterostomy technic of choice for drainage of the intact bowel is that described by Witzel, with a 16 or 18 French soft rubber catheter or a rubber tube of comparable size. When possible, the omentum should be interposed between the suture line in the intestine and the abdominal wall. Such an enterostomy seldom leaks and will quickly close when the tube is removed. All suturing of a distended intestine should be very carefully done to avoid tearing or pressure necrosis. Aspiration of the distended loop with a trocar before sutures and tube are placed will avoid soiling.

In general, it is best to place an enterostomy near the site of the obstruction. Frequently, however, the exact location of a small bowel obstruction cannot be determined with safety. Rather than subject an ill patient to extensive exploration, it is usually wiser to choose the first loop of distended bowel presenting through a right or left rectus incision and drain at that point.

CONCLUSIONS

1 High jejunostomy may be adequately replaced by an indwelling tube in the stomach or duodenum through which may be aspirated the stomach and regurgitated upper intestinal content.

2 In properly selected cases, an enterostomy is a valuable operation and may be life saving. It must neither be considered to be a court of last appeal nor be expected to bring back to life the moribund. There is a danger in too much dependence on enterostomy to the exclusion of more logical treatment.

3 Enterostomy cannot be successful if the intestine is paralyzed.

4 Enterostomy is indicated to drain a distended intestine of gas and liquid to prevent overdistention and not primarily to drain off toxic material within the bowel to prevent absorption. Absorption of toxins from an obstructed bowel does not begin until the circulation of the bowel wall is impaired, after which enterostomy is usually unsuccessful.

406 West Thirty-Fourth Street

ABSTRACT OF DISCUSSION

DR W. D. GATCH, Indianapolis. I wish to express agreement with all of Dr Orr's conclusions. I have been interested in the study of the effect of distention of the bowel on the circulation through the bowel wall and on absorption from its lumen. I have demonstrated that gangrene of the bowel can be produced by distention alone without interference with its mesenteric circulation. In intestinal obstruction, distention of the bowel is the one condition that must be relieved, as Dr Orr has emphasized before the bowel is paralyzed and unable to move its contents of gas and fluid to the enterostomy tube. In cases of advanced obstruction from any cause, enterostomy will be of value if audible borborygmi are still present. If none can be heard it is probably too late to hope for benefit from the operation. However, I think that even in these extremely advanced cases the operation should be done. It may do some good. The modern nonleaking aseptic enterostomy is one of the most useful of operations. Its use in advanced appendicitis will greatly diminish the death rate. It will also rescue many neglected cases of mechanical ileus. I have been doing enterostomy in advanced appendicitis for a number of years. I find that it is not necessary in many cases even when the case is seen at operation to be far advanced. I rarely do an enter-

ostomy at the time of appendectomy. I watch the patient's course after operation very carefully and listen to the abdomen at frequent intervals. As soon as the patient vomits material that has an odor I at once consider the possibility of enterostomy. I find it a great help to take a flat plate of the abdomen at that time to see the gas patterns. If the plate shows loops of small bowel which have a diameter of from $2\frac{1}{2}$ to 3 inches, I think enterostomy should be done at once. It should be done at a time when one still hears good, loud borborygmi. My results under these conditions have been uniformly good. The advantages of the Witzel operation are that it can be done without risk under local anesthesia even on a moribund patient and that it requires no secondary operation to close the opening in the bowel.

DR J. SHELTON HORSLEY, Richmond, Va. One of the most valuable contributions to the study of intestinal obstruction in the last two decades has been made by Dr Orr and his associates. His accomplishments have been both negative and positive. He has shown the necessity of preventing the marked fall of blood chlorides in high obstruction and this by giving salt. The negative contribution has been exploding the theory of a specific toxic material as the cause of the symptoms of obstruction. Dr Gatch has called attention to another indication for enterostomy, that of feeding, but enterostomy in obstruction finds probably its most important field, especially in postoperative obstruction. Lymphatic adhesions coming on a few days after operation usually clear up in a week or two but in the meantime enterostomy is demanded. Obstruction that occurs long after an operation, a month or more, or without any operation, should be thoroughly explored, because not infrequently beginning gangrene or a volvulus or some other lesion exists that could not be recovered from without a radical procedure. Enterostomy in these cases, however, is extremely valuable as an adjuvant because if there is marked distention there is also an impairment of peristalsis, and even though the obstructive lesion may be removed the bowel may not be able readily to empty and has to be helped along. In addition to absorption from the intra-intestinal pressure, it must be remembered that in peritonitis there is also peritoneal absorption. With a septic exudate in the peritoneal cavity the pressure of the distended bowel will force into the peritoneum more of the toxic material from the peritonitis than if the bowel were not distended. So enterostomy has an indication to relieve not only the intra-intestinal pressure but the external pressure as well. The oblique enterostomy with a tube is usually excellent in obstruction. When, however, it is necessary to do an enterostomy in order to rest the colon as in the multiple stage operation on the colon for malignant conditions, I think the best thing is to bring up through a muscle-splitting incision the ascending colon onto the abdominal wall, put a glass rod under it, probably suture in a catheter for a day or two, and then incise the cecum, so that absolutely all the intestinal contents are voided through the enterostomy and complete rest is given the distal colon. In two or more weeks a resection is done, and in the third stage the enterostomy is closed. In the technic of Dr Orr, the catheter is transfixed with the last external intestinal suture. This may be a potential source of infection for it is not fully protected from the peritoneal cavity. I place a purse-string suture, perforate the intestine within its grasp, close the purse-string suture, and then transfix the catheter with the end of the purse-string suture. The catheter is then buried by a row of sutures and the point of transfixion is thus fully covered. After this is done a fine catgut suture placed just where the catheter emerges from the bowel is passed through the parietal peritoneum. There is then no necessity of bringing the omentum over the enterostomy, and the operation seems to be about as safe from the production of peritonitis as it can reasonably be.

DR GEORGE A. HENDON, Louisville, Ky. Statistics have appeared in the literature which seemed to indicate that more patients die when enterostomies have been performed on them than when in similar circumstances these were not done. It is also an indisputable fact that more patients die on whom medical consultations have been held than those who had no medical consultations for the simple reason that in most cases consultations are resorted to after the battle is lost. If enterostomies were performed at the right time there would be

a very material and striking change in the mortality statistics. By the right time I mean the time when the primary operation is performed. I think that surgeons should have judgment enough to select the cases in which an enterostomy would be of advantage. Because I did not possess that judgment, I have gone to the trouble of devising an operation that is so simple that if it does not do any good it surely cannot do any harm. Dr. Rankin was kind enough to include an illustration of this operation in the new work on the colon and rectum, by Rankin, Buie and Bergen. Any operation that contemplates the transfixion of an intestinal wall to a rubber tube is mechanically unsound, for the simple reason that it is a fundamental principle that when substances of unequal density are bound together the one with the least density will yield when there is any stress or strain exerted on it. Most of the intestines requiring enterostomy have disintegrated walls, and the slightest tension will produce a tear, through which leakage will occur. When convalescence is established the catheter can be removed if it comes out easy, or it can be cut off even with the abdominal wall and dropped inside the bowel to be evacuated through natural channels. I recommend this operation because it is simple and one need not hesitate to do it in doubtful cases. It never leaves a fistula.

ECTOPIA LENTIS

WITH REPORT OF A CASE OF TOTAL DISLOCATION,
DIRECTLY DOWNWARD

WARREN D. HORNER, M.D.

AND

SOL MAISLER, M.D.

SAN FRANCISCO

Ectopia lentis is a congenital displacement of the crystalline lens of comparatively rare occurrence, it must be distinguished from the acquired dislocations which develop spontaneously or as the result of trauma. Ectopia of the lens is ordinarily bilateral and symmetrical in both eyes. Knapp's¹ statement of its occurrence as approximately 1 in 5,000 cases denotes the rarity of the condition. The oldest reference found in the literature pertaining to ectopia is that of von Graefe,² who, in 1854, described the condition and called particular attention to its hereditary nature. The German and the English schools are amply represented in the early reports, the former by Stellwag von Carion's paper,³ which appeared in 1856, and Sippell's⁴ book, which was published in 1859, the latter by Dixon's⁵ report in 1857 and Jeaffreson's⁶ report in 1871. Although articles have appeared almost yearly since these early dates, they have failed to include a comprehensive bibliography.

The strong hereditary tendency in ectopia lentis is well emphasized by several authors. Morton⁷ recorded its occurrence in five successive generations comprising ten persons. Lewis⁸ found sixteen cases in six generations of one family. Adams (quoted by Folk⁹) reported observation on a family of nine children, seven

of whom had dislocated lenses. Cameron,¹⁰ reporting on four successive generations, found fourteen persons affected, of whom only one was a male. In regard to transmissibility, Folk⁹ stated that of marriages between twenty-two affected and nonaffected parents, seventeen offspring were affected, proving a ratio of almost three to one. It is believed that the condition is more common in Anglo-Saxons than in persons of the Latin race, and also that a majority of the patients are intelligent and of good health, with the possible exception of other associated congenital diseases of the eye.

Several theories have been advanced concerning the causative factors of ectopia. These are reviewed in Kennedy's excellent paper.¹¹ He stated that most observers concurred with the theories first offered by von Graefe and Quaglini with reference to a developmental defect in the suspensory ligament. This defect is occasioned by a faulty or delayed closure of the ocular cleft. In considering the stages in development of the suspensory ligament, it may be recalled that the primitive lens remains in contact laterally with that portion of the secondary optic vesicle subsequently destined to become the ciliary body. The lens becomes encircled by a fibrovaseular sheath which forms adhesions from contact with a portion of the secondary optic vesicle. As the eyeball enlarges, it does so at a greater rate than the lens. Consequently, that portion of the ciliary body which was in contact with the lens grows away from it, and the adhesions previously formed between them become stretched, to become the delicate fibers of the suspensory ligament. In explaining an upward dislocation, it may be assumed that the absence of fibers of the zonule of Zinn in the inferior region offers no resistance to the pull upward on the lens. According to the theories of Hess and Treacher Collins, displacement may also be occasioned when the adhesions between the ciliary body and the margins of the lens are denser and less elastic on one side than on the other, so that they expand less readily than the opposing ones. This would account for the cases of ectopia in which the fibers of the suspensory ligament are seen in the aphakic area. Another etiologic factor may be that of traction of the hyaloid artery and bands in the vitreous. Badal and La Grange believe that all such eyes are myopic and the lens is too small for the space it should occupy. As a result, the overstretched zonula yields and the lens is displaced in the direction of least resistance. However, contrary to this belief of a small lens, Lindner (quoted by Parsons¹²) has reported four cases in which the lenses were larger than normal.

In reviewing the causes of developmental anomalies, Collins and Mayou¹³ aptly stated, "At present we are unable to say what causes the usual orderly cycle of transformations which ensue after the fertilization of the ovum and consequently, frequently unable to account for disorderly occurrences in that cycle. It is perhaps more surprising that such a complicated structure as the eye should so often develop in a uniform way than that occasional irregularities should occur." Relative to ectopia, the work of biologists such as Guyer, Stockard (quoted by Kennedy¹¹) and others becomes sig-

nificant. It is known that during the second week of embryonic development, the primary optic vesicles become differentiated, appearing as offshoots from the forebrain. Ideas differ as to how this is brought about. Stockard, from his experiments, believes that the cells responsible for the formation of the eyes have their origin in the median plate of the central nervous system. By excising a portion of this structure, he could prevent the formation of eyes. Early removal of a lateral portion of the plate, however, did not prevent formation of eyes nor displace the optic vesicles, which were found to be situated laterally as usual.

By exposing fresh fish eggs to heat, cold and chemical fumes, Stockard found that he was able to obtain arrest of development of the optic vesicles ranging from cyclopia to essentially normal eyes. The end-result depended on the period of development at which the inhibiting agent was introduced.

Guyer pulverized rabbits' lenses and injected them into fowls. When serum of these lens-sensitized fowls was next injected into pregnant rabbits, the offspring showed abnormalities such as coloboma of the iris and choroid, cataracts and displacement of the lenses, together with variations in the size and situation of the globe. By mating these defective rabbits, he obtained progeny with abnormalities which tended to increase in succeeding generations. He has succeeded in carrying a defect through nine generations and believes that when once obtained, the defect can be transmitted indefinitely.

In ectopia lentis, the direction in which dislocation may occur varies and, as stated heretofore, is usually symmetrical in the two eyes. Of seventy-three cases reported by Dorsch,¹⁴ displacement upward in both eyes occurred in thirty, up and out in eighteen, up and in in eight, down in five, inward in four, outward in three and down and out in one. In one case the right lens was inward, while the left one was down and in. Three cases showed asymmetrical displacement. Two of these showed the right lens down and out, while the left was down and in. In the third case, the right lens was down and in but the left was up and in. Collins and Mayou¹⁵ stated that displacement never occurs directly downward, although in one of Adams' cases, mentioned by Hardy,¹⁶ such a dislocation is described. In 1874 Page¹⁷ reported a case of unilateral ectopia lentis.

The edge of the lens in ectopia may or may not occupy the pupillary region, its margin being seen in certain instances only after dilatation of the pupil. The existence of ectopia lentis may be suggested primarily by the accompanying iridodonesis. In large pupils which reveal an edge of the lens this aperture is divided into an aphakic and a phakic portion with a resultant monocular diplopia. The anterior chamber is deepest on the aphakic side, the side from which the lens is displaced. By reflected light the edge of the lens appears as a dark crescent, owing to the prismatic refraction. In many cases the suspensory ligament is completely absent in the region corresponding to the aphakic area, the lens being dislocated away from the point of the absent zonule. Absence of the suspensory ligament produces a movable lens which may push forward and interfere

with the passage of fluids through the pupil and thus produce a rise in tension. Isnel Deschamps and Clerc¹⁸ reported such a condition in two sisters presenting congenital dislocation of the lens accompanied by glaucoma. Iritis may result from the migration of the lens into the anterior chamber. Allport and Smith¹⁹ noted a case of bilateral luxation of the lens in which this structure was entirely unattached and would float freely through the dilated pupil into the anterior chamber or return to its fossa according to the position of the child's head. As seen with the ophthalmoscope, the curved edge of the lens is not always regular, but may show slight depressions or elevations. The depressions in the border may amount to a notch, constituting a coloboma of the lens, as reported by Clark²⁰ and Giri.²¹ Other associated defects which may occur with ectopia lentis are coloboma of the iris, usually in the opposite direction, corectopia, iridemia, nystagmus and a persistent hyaloid artery. Crebbin²² reported a case of congenital dislocation showing opaque lenses and a persistent pupillary membrane. The lenses, however, are usually clear in ectopia lentis in contradistinction to the loss of transparency seen in traumatic dislocations.

Corrective measures for ectopia lentis consist primarily in refraction and secondarily in surgical treatment in appropriate instances. The refraction in typical cases is myopic owing to the unopposed elasticity of the lens. This is well illustrated in a case reported by Hess (quoted by Parsons,¹² which presented a myopia of 15 diopters in the phakic area while the aphakic area measured plus 10 diopters. Clark,²⁰ who studied the refraction in a series of cases over a period of years, found that the myopic component remained stationary. There was, however, a periodic variation in the cylindrical correction owing to changes in the lenticular astigmatism. This was due, in his opinion, to a shifting of the lens in its hyaloid fossa. The results of refraction are, however, for the most part disappointing because of the accompanying amblyopia, a finding commented on by Jeaffreson⁹ as early as 1871.

The surgical problems include needling or extraction of opaque ectopic lenses and the relief of secondary glaucoma. Needling entails transfixation of the lens by a second needle while a capsulotomy is being performed. Isnel, Deschamps and Clerc¹⁸ have reported cases of glaucoma in which the patients were successfully treated by sclerocorneal trephine. The use of Heine's cyclo-dialysis may be considered in appropriate cases.

The following case is reported not only because of the general rarity of ectopia lentis, but more particularly because of the unusual displacement directly downward. As previously noted, Dorsch¹⁴ found only 5 such instances in a total of 73 cases. Assuming that ectopia lentis occurs once in 5,000 cases (Knapp¹) and that only 5 in 73 are dislocated downward, the incidence of the case reported would appear to be about 1 in 73,000. Some authors apparently do not follow Dorsch's statistics (1900), for as late as 1911 some authorities deny that congenital dislocation ever occurs directly downward.

REPORT OF CASE

History—L. L., an American boy, aged 10, was seen in consultation at the San Francisco Hospital in February, 1932, while under treatment for osteomyelitis of the femur. Poor vision and tremulous irises were noted during the general physical examination. Only the condition of the eye will be described here.

The parents were Italians and were living and well. One brother, aged 6, was normal. No congenital deformities were known in the parents' families.

The patient's birth was normal. He had no illness until 9 years of age, when osteomyelitis of the left femur required hospitalization for nine months. At the time of examination he walked without a crutch. There was no history of injury or accident. The Wassermann reaction was negative. He was noted as a baby to hold objects very close to the eyes. He first wore glasses at the age of 7. He was in the 4 A grade sight-saving class, and made satisfactory grades.

Ocular Examination—Vision in the right eye was limited to the perception of fingers at 13 feet, with +10.00 sph \ominus +2.50 cyl 90°, vision was 0.3. Vision in the left eye was limited to the perception of fingers at 8 feet, with +10.00 sph \ominus +3.00 cyl 100°, vision was 0.3. Examination for near vision showed J 150, with correction and +3.00 add J 75, in the two eyes.

Neither eye showed injection. The movements of the eyes were normal. The pupils were equal and regular but were slightly oval in the vertical diameter. They reacted normally to light, and showed a slight but definite reaction to convergence. There was coarse iridodonesis in each eye when the patient looked to the side. The anterior chambers appeared of similar depth throughout. The right eye showed a flagellum-like strand of persistent pupillary membrane attached to the lesser circle of the iris. It was not present on the left. The irises showed no coloboma. Tension (Schiotz) was 20 mm in both eyes.

Examination of the Fundi—The right eye showed fine, floating, dustlike vitreous opacities. The lens was completely subluxated directly downward, no margin of the lens was seen in the pupil. About two thirds of the upper circumference of the lens was visible, appearing to be at the level of the ciliary body. The edge appeared regular and pigmented and contained a few dark fringe-like strands which looked gray under direct illumination and which extended free into the vitreous. The lens appeared perfectly transparent, retinal vessels being clearly seen through it, and was in the erect position. It oscillated with the vitreous, but assumed a constant position in relation to a particular retinal vessel which was used as a reference point. With the head tipped backward over the edge of a table, the lens still remained below the pupillary margin.

The fundus details were quite clear. The disk was oval in its vertical diameter and was sharply demarcated except temporally, where there was a lighter crescent about one-half disk diameter in width, nasally there were a few flecks of pigment belonging to the choroidal ring. The retinal vessels appeared normal. The macula contained numerous yellowish areas of depigmentation, some of which appeared streaklike in a horizontal direction. There were also occasional dotlike pigment deposits, which, together with the depigmentation, established the diagnosis of old, central chorioretinitis. The peripheral fundus was clear.

The left eye showed an identical vitreous. The dislocation of the lens was similarly directly downward, but a trifle lower than on the right. Its edge appeared clean cut, regular and dark but contained no grayish fringe, which was so noticeable on the right. It was equally transparent and erect. With the head tipped backward over the edge of a table, however, the upper edge of the lens became just visible in the pupillary area, but returned to its original position when the patient assumed the erect status.

The disk was oval vertically and had a similar temporal crescent, showing choroidal vessels and a few pigment granules. The macula showed some increased pigmentation but no definite lesions.

One was unable to see any part of the lens by the slit lamp. Perimetric fields showed no appreciable defect. Color vision

and gross stereoscopic vision were normal. The ophthalmometer readings were right eye, $87^\circ \pm 3.50$, left eye, $100^\circ \pm 3.2$. Refraction was typically aphakic.

R	E	+	10.00	sph	\ominus	+2.50	cyl	90	V	0.3	partly		
L	E	+	10.00	sph	\ominus	+3.00	cyl	100	V	0.3	partly		
										Add	+3.00	J 75	0

Since this result was at variance with the old glasses, a new prescription was given with a plus 3.00 added in a ground bifocal. The patient had previously been wearing a +9.00 sphere with +1.75 cyl 90° for both eyes.

During the past year the patient has made a noticeable improvement in school work (sight-saving class), he is quite comfortable with the bifocals. Corrected vision is now 0.3 partly in each eye and J 62.

SUMMARY

A case of congenital, bilateral, total dislocation of the lens is reported in a boy of 10, the dislocation being directly downward. This position is stated to be exceedingly rare by most authors, while its existence is denied by some. It is accompanied by an old monocular chorioretinitis and a partial persistent pupillary membrane but by no other congenital anomalies, nor by glaucoma.

In order to overcome the aphakia, bifocal lenses were prescribed and have been successfully worn for the past year, with definite improvement in both distant and near vision.

ABSTRACT OF DISCUSSION

DR WILLIAM ZENTMAYER, Philadelphia. This, I believe, is the first time since 1898 that this subject has been brought to the attention of the section. The outstanding feature of this anomaly is its hereditary and familial tendency. Instances even more striking than those noted by the authors have been reported. R. M. Gunn records its occurrence in seventeen members of five families of twenty-two children. Dehene and Baillart report a history of four generations affected in which all the six descendants of the first showed double luxation. There are a number of similar case histories in the literature. The descent seems not to be of like nature in all cases. Gunn states that in his case it was not a mendelian recessive. In two families it acted as a pure dominant. In Francheschetti's case it was a recessive hereditary condition manifested through consanguinity, while Kotlarveskard, basing his observations on thirteen cases, considered it of a hereditary dominant type. Whatever the genesis of the condition may be, two factors are significant: the occurrence at times of a coincident ectopia, and the frequent association of myopia, 60 per cent. The first would indicate the persistence of a mesodermal strand as the cause of both anomalies, and the latter a stretching of an inherited weak zonule as the more the eye stretches the more the fibers are stretched. This probably accounts for the fact that the ectopia increases with time and in many instances becomes a complete luxation (Rotth). The myopia is not in every case axial but as stated by the authors may be lenticular. In one of my cases the fundus presented myopic changes. Butler, Mesmann and Hegner report instances of downward dislocation. In a number of cases there was a deformity of the skull, sometimes associated with impaired mentality. Operation, when called for by secondary glaucoma or because of cloudiness of the lens presents difficulties. The statement that needling entails transfixation is a correct generalization, but in individual cases needling as ordinarily done has been successful. I have notes of only two cases in which operations were performed. In 1926 I operated on a girl, aged 7 years. The lenses were dislocated downward and inward and were cloudy. Three dissections were performed on the left lens and absorption resulted. The second case was that of a boy, aged 16 years. The lenses were dislocated downward and inward. There was noncongestive secondary glaucoma. A simple extraction with a loop was safely accomplished in the left eye with a resulting active round pupil. Visual acuity equaled 6/20. As a result of this success the other eye was similarly operated on and lost through iridocyclitis resulting in atrophy of the globe.

VITAMIN B DEFICIENCY AND THE
ATROPHIC TONGUE

ADOLPH M HUTTER, MD

AND

WILLIAM S MIDDLETON, MD

WITH THE COLLABORATION OF

HARRY STEENBOCK, PhD

MADISON, WIS

Glossitis with atrophy of the lingual papillae to ultimate baldness constitutes a conspicuous manifestation of a number of diseases. Recent occasion¹ has been taken to review this subject. Among the conditions in which the atrophic tongue has been described are pernicious anemia, achlorhydric anemia, anemia of pregnancy, pellagra, sprue, Plummer-Vinson syndrome, malnutrition attended by dysentery and anemia, intestinal stricture, pyloroplasty complicated by peritonitis, *Dibothriocephalus latus* infestation and achlorhydria. In the quest of an explanation for this interesting phenomenon such an array of conditions may be confusing, yet it offers certain points of logical attack on the problem of pathogenesis.

For a long period the infectious background of the glossitis of pernicious anemia was accepted on the basis of the work of Hunter² and of Schneider and Carey.³ Later, Wilkinson and Oliver⁴ and Oatway and Middleton⁵ observed a definite relationship between the incidence of achlorhydria and glossitis. Witts,⁶ on the other hand, pointed out that, whereas gastric acidity was the usual concomitant, cases of anemia and malnutrition were available in which the glossitis appeared with normal gastric acidity. Minot and

recurrences of glossitis even while the patients were on liver therapy. Hence they concluded that "liver does not seem to be entirely specific for this symptom." The inclusion of sprue and pellagra among the diseases characterized by the atrophic tongue immediately suggests the possibility of a deficiency explanation for this manifestation in the entire group. Moersch and Conner⁹ invoked a dietary background for the changes incident to "hysterical dysphagia." Ungley¹⁰ called attention to an obvious parallelism between pellagra and pernicious anemia in their common glossitic and gastro-intestinal manifestations. He concluded that these symptoms in pernicious anemia might well result

Fig 2—Section of normal rat tongue (Courtesy of Dr Gorton Ritchie)

from a metabolic disturbance or from a deficiency rather than from an infection.

Castle's¹¹ epochal work advanced sound evidence that, as a rule, the actual fault in pernicious anemia resides in the subject and not in his diet. An absence of the intrinsic factor in the gastric juice of patients with pernicious anemia renders them incapable of assimilating from the diet certain elements necessary for orderly erythropoiesis. Later Strauss and Castle¹² concluded that the extrinsic factor "may now be defined as a substance closely related to vitamin B₁₂, if not vitamin B₁₂ itself." Interestingly, Gerstenberger¹³ had previously observed a favorable response of aphthous and ulcerative stomatitis to water soluble vitamin B. Two of his reported cases showed an acute glossitis which likewise improved under this therapy. Lewis's¹⁴ survey of this subject was most comprehensive and he concluded that the smooth tongue in all probability represented a deficiency manifestation. He made a further important observation in a patient with sprue who presented the blood picture of pernicious anemia. The tongue of this patient was normal and the gastric juice contained free hydrochloric acid, pepsin and rennin. However, when this gastric juice was incubated with 200 Gm of beef and fed to a pernicious anemia patient, no remission occurred in the blood picture. The product of the interaction between normal

Fig 1—Section of rat tongue after thirty-nine days on a vitamin B deficient ration (Courtesy of Dr Gorton Ritchie)

Murphy⁷ reported the complete remission in the glossitic manifestations of patients with pernicious anemia receiving liver. Isaacs, Sturgis and Smith⁸ noted mild

gastric juice and beef, on the other hand, subsequently induced a prompt reticulocyte response in the same patient. Lewis concluded that the absence of the intrinsic factor did not explain the lingual atrophy.

The deficiency theory seemed the most fruitful point of attack on the problem, and at the time of the institution of the experimental study (December, 1931) it was deemed logical to investigate the influence of vitamin A deficiency on the tongue because of the evi-

Fig 3 (case 1)—Tongue prints A before treatment B after high vitamin B diet

dence of an infectious background adduced by Hunter,² and by Schneider and Carey.³ A Pavlov pouch was prepared in a dog's stomach by Professor J. A. E. Eyster to render frequent determinations of the gastric acidity possible. After certain inconsequential preliminary studies, a biopsy of the dog's tongue was taken, Feb. 16, 1932, and the animal was placed on a diet deficient in vitamin A for a period of three months. A second biopsy was then taken and no microscopic changes were observed in the surface markings or in the deeper structures of the tongue.

Fowls were suggested as the most available experimental subject for vitamin B studies, but certain technical difficulties presented themselves, particularly in the osseous tissue in the chicken's tongue. Accordingly, the rat was the next choice by reason of the highly serrated papillae that characterize the anterior two thirds of the dorsum of the tongue. Through our colleagues in the department of agricultural chemistry, materials have been made regularly available after varying periods of standard vitamin B deficient rations. A number of rats were fed on a low vitamin B diet.¹⁵

Fig 4 (case 2)—Tongue prints A before treatment B after parenteral liver extract

After a period of thirty-nine days, and earlier in certain instances, these rats were observed to become scrawny and malnourished and to manifest polyneuritic symptoms. The tongues of these animals presented a

¹⁵ At present a group of rats is being fed a low vitamin B diet in an attempt to assign the specific responsibility for the atrophic glossitis. After the completion of our observation on the effect of vitamin B deprivation the preliminary report of Miller and Rhoads in the experimental production of sprue in dogs fed on a vitamin B deficient diet appeared, (Proc. Soc. Exper. Biol. & Med. 30: 540 (Jan. 1933)) and gave conclusive evidence of a glossitic reaction to this deficiency with ultimate papillary atrophy of a marked degree. Such evidence as our experimental studies on vitamin B deficiency in the rat may reveal will constitute a further report.

smooth and bald appearance as compared to the normal rat, whose papillae give the tongue a finely stippled, uneven appearance. The rats were killed. The characteristic microscopic picture is conveyed in figure 1. A section of the normal rat tongue is shown in figure 2 for comparison. Without exception there has resulted a marked degree of papillary atrophy, and this change has advanced to virtual effacement in certain instances. In areas of some tongues, denudation by ulceration has occurred. To check these observations a second group of rats was fed a similar low vitamin B diet over a period of from ten to eleven weeks. The microscopic studies of the tongues of this group revealed changes similar to those in the first group. A third group of young rats was fed a similar diet for the same length of time, and it is interesting that these rats developed a lesser degree of lingual atrophy than did the older rats for the same period of B deprivation. It is interesting that the round-cell infiltration and fibrosis of the tongue in pernicious anemia has not been completely reproduced in this experimental series. The time factor may enter into this discrepancy in the picture.

The clinical study of the atrophic tongue has been closely pursued for the past three years.¹⁶ Tongue prints on smoked paper have afforded permanent records of the progress of this condition under varying forms of therapy. Accordingly, following the same

Fig 5 (case 3)—Tongue prints A before treatment B after parenteral liver extract

technic,⁵ it was possible to evaluate the clinical application of the experimental evidence of a vitamin B deficiency in atrophic glossitis.

CASE 1—The first patient encountered in this study presented the classic picture of pernicious anemia. His tongue showed marked atrophy with flattening of the fungiform and filiform papillae anteriorly but was not completely bald. A tongue print was taken (fig. 3 A) and the patient was placed on a high vitamin B diet supplemented by one compressed yeast cake twice a day. For the period from Jan. 27 to Feb. 8, 1933, this regimen obtained and liver therapy was withheld. The blood count underwent a slight slump (from 2,270,000 to 1,920,000 erythrocytes) but there was an appreciable regeneration of the papillae, and the normal tongue markings were almost completely restored in this short time (fig. 3 B). The hematopoietic response on the initiation of liver therapy was prompt and satisfactory.

CASE 2—A patient with pernicious anemia showing similar lingual atrophy was placed on a high vitamin B diet without liver. As demonstrated in the tongue prints taken on admission (fig. 4 A) there was flattening and atrophy of the papillae over the anterior two thirds. After two weeks' time there was no appreciable change in the gross appearance of the tongue or in the prints. The subsequent addition of diluted hydrochloric acid effected no apparent benefit over a further period of ten days. As demonstrated by the tongue print (fig. 4 B) a slow return of papillae ensued on the addition of liver therapy in the form of a parenteral extract, but it did not parallel the hematopoietic response.

CASE 3—A patient with pernicious anemia presented an atrophy of the lingual papillae in the anterior and central portion of the dorsum on admittance (fig 5 A). The tongue was sensitive to touch. His condition was too precarious to defer liver support, but an effort was made to maintain a low vitamin B diet. The response of the erythropoietic centers was brilliant. On the fourth day after 20 cc of liver extract intramuscularly (equivalent to 100 Gm of whole liver), the reticulocytes rose to 148 per cent and the succeeding day reached 35 per cent. By the sixth day there was early evidence of regeneration in increased prominence of the fungiform papillae. Virtual normality of the gross appearance in the tongue was attained by the eleventh day. The tongue also lost its sensitivity (fig 5 B).

Clearly, certain divergences present themselves in this group of three cases of pernicious anemia. The prompt response of the glossitic manifestations of the first case on a high vitamin B intake without specific therapy directed toward the underlying anemia bespeaks a pure deficiency background. In the next two cases, however, other circumstances arise. In the second no response was observed on a high vitamin B diet, but the slow response on a low vitamin B diet intake with coincident liver therapy suggests a conditioned deficiency, in which event the absorption or assimilation of the lower B intake may be rendered more adequate by liver extract. The initial trial of a high vitamin B intake without liver was denied in the third case, but a similar explanation to that advanced in the second case may apply here. Finally, in both instances the parenterally administered liver extract may have had an independent action. West¹⁷ has reported the presence of vitamin B₂ in liver extract.

CASE 4—An unusual situation presented itself in this patient, who was admitted for the study of a grave anemia that had responded to desiccated hog stomach before entrance to the hospital. The case proved to be one of gastric polyposis presenting a completely bald tongue, achlorhydria and hypochromic anemia (38 per cent hemoglobin and 3,080,000 erythrocytes). The surface of the tongue was smooth and glistening, figure 6 shows an absence of the papillary markings. The patient was given a high vitamin B diet without liver but supplemented by one compressed yeast cake twice a day. In six days there appeared a series of innumerable pin-point white dots on the tongue, and when it was dried, these were shown to be slightly elevated above the surface. Unfortunately, these changes could not be demonstrated by the tongue prints. Further observation was rendered impossible by the discharge

Fig 6—Tongue print showing complete lack of papillary markings

of the patient, but this apparent response constitutes the earliest in our experience. CASE 5—A patient with advanced ulcerative pulmonary tuberculosis suffered from intermittent diarrhea dependent on ileocecal tuberculosis. The tongue was completely bald (fig 7 A), and a hypochromic type of anemia prevailed (52 per cent hemoglobin and 5,150,000 erythrocytes). The gastric acidity registered 18 degrees of free hydrochloric acid. On a high vitamin B diet with added compressed yeast, regeneration of the lingual papillae occurred whenever the diarrhea could be controlled for a few days. The first evidence of regeneration was noted in the middle third of the dorsum of the tongue with the appearance of flat fungiform papillae (fig 7 B). A remission of the diarrhea was early followed by the relative denudation of the tongue (fig 7 C). Several cycles of this order were observed.

Such prompt fluctuations in the lingual markings incident to the enteric state argue against a neurogenic explanation of the former. Apparently the factor of absorption conditions this deficiency in the presence of an adequate vitamin B intake.

These characteristic experiences lead to the conclusion that the atrophic tongue is dependent on a vitamin B deficiency. Experimentally, the condition has been regularly reproduced in rats on a vitamin B defi-

Fig 7—Tongue prints. A before treatment. B after a high vitamin B diet. C high vitamin B continued but relapse in enteric condition.

cient ration. Clinically, the problem is not as clear cut. Instances of pure vitamin B deficiency will respond to an excess of the lacking substance. If the deficiency is conditioned by factors of impaired absorption and assimilation, the addition of the deficient vitamin to the diet may not be sufficient in itself to overcome the basic fault.

The work performed by Ivy and his associates¹⁸ on experimental gastrectomy establishes the narrowing of the margin of safety in erythropoiesis by this surgical procedure, so that anemia develops regularly in such animals under the strain of pregnancy. Analogous conditions may exist in pathologic states of the gastrointestinal tract to explain the improper assimilation of vitamin B, which is apparently required to maintain the normal lingual papillae. Certain evidences of minor relapses have been reported by Isaacs¹⁹ in patients with pernicious anemia receiving liver therapy. These symptoms include, among others, glossitis, anorexia, diarrhea and constipation. The fact that such relapsing manifestations occur seasonally (March most frequently) suggests a vitamin responsibility and indicates further a decidedly reduced reserve. Lastly, the apparent inconsistency of papillary regeneration on the parenteral injection of liver extracts after the failure of a high vitamin B diet alone to induce such a change may depend on the presence of vitamin B₂ in the liver extract or on an improved assimilation of the available vitamin B from the diet through the mediation of the parenteral extract. These circumstances add a further

ABSTRACT OF DISCUSSION

DR FRANK D GORHAM St Louis The subject of vitamins and their relation to the so called deficiency diseases has become so complicated that most of us are unable to follow with any degree of orientation the course of events To me this is particularly true of vitamin B which is believed to be a factor in at least thirty metabolic disorders This deficiency may be due to improper diet or may be a result of our civilization or faulty machinery of a particular individual This investigation has led the authors to the conclusion that atrophic glossitis is most probably dependent on a vitamin B deficiency They were able to produce this condition in rats by withdrawal of vitamin B from the diet In the human being however their clinical studies were less conclusive but do suggest a possible fruitful field for further investigation They call attention to the fact that in man atrophic glossitis may occur in many conditions other than pernicious anemia Contradictory, and of especial interest are those patients who show free hydrochloric acid in the stomach

DR WILLIAM S MIDDLETOWN Madison Wis The discussion of Dr Gorham is sincerely appreciated We realize of course that the human subject is not the rat We appreciate, too, that there is some discrepancy in a further part of the question which we did not discuss in detail namely that our first results on B deficient rations in the rat have produced only inadequate atrophy of the papillae as compared with the results of Miller and Rhoads in their experimental sprue in dogs We are not convinced, in other words, that this is the only factor We know that B deficient diets can in rats produce the glossitic condition histologically which we recognize clinically in the several conditions that have been mentioned I believe that an open mind should be kept as to the mechanism of action as well as to the agent that is responsible for the entire story

TUBERCULOSIS OF THE GREATER TROCHANTER

HENRY W MEYERDING, M D

AND

RUDOLPH J MROZ, M D

Fellow in Orthopedic Surgery the Mayo Foundation

ROCHESTER, MINN

Tuberculosis of the greater trochanter causes localized pain and tenderness associated with swelling, which must be distinguished from tumor and other forms of infection It is common for the bursae about the trochanter to become involved, with a resulting fluctuating mass containing serum and broken down debris, more rarely, extension into the femoral neck or hip joint is the result

The literature on the subject is rather meager and consists largely of reports of cases in one report eleven cases of tuberculosis of the trochanter were presented Teale,¹ in 1870, described a case of tuberculosis of the bursa over the greater trochanter in which the gluteal tendon appeared to be a factor in pro-

longing the disease of the bursa He advised division of the structure for the purpose of removing all muscular tension In 1903, at which time he² reported another case, he mentioned the possibility of confusion of tuberculosis of the bursa and tuberculosis of the hip joint itself Thurston,³ in 1907, reported a case of bilateral tuberculous bursitis of the bursa, treated by excision with good results Wieting⁴ in 1904, reported the largest series of cases of tuberculosis of the greater trochanter and its bursa that had been reported to that time He believed that trauma, induced by the customary sitting posture assumed by the Turks, who made up his patients, was an important contributing factor in the etiology of the disease He stated his belief that the primary infection is usually in the trochanter and that it may spread by continuity to the bursa If the bursa only is explored and no apparent connection can be found leading to the bone, this is probably due to the fact that the tract through which the infection had passed had been plugged or healed He observed that in cases in which apparently only infection of the bursa existed, perfect healing followed surgical treatment

Cone,⁵ in 1911, spoke of the formation of rice bodies in bursa in connection with tuberculosis of these structures He also mentioned "primary sclerosing tuberculosis" of the bursae as described by Reinhardt,⁶ a condition we have not observed Clopton,⁷ who reported three cases in 1919 concluded that tuberculosis of the greater trochanter usually does not occur in childhood, and he stresses the probability of trauma as an etiologic factor, from the standpoint both of external trauma and of the trauma of muscle pull Swindt,⁸ in 1921 reported one case and also stressed trauma as an etiologic factor, in that infection is usually secondary to trauma Peabody,⁹ in reporting two cases brought out the importance of making a differential diagnosis of tumors and tuberculosis of the trochanter He also advised early intervention and excision of the affected area before the formation of sinuses Keith,¹⁰ in reporting a case, felt that the history physical manifestations and roentgenograms pointed to neoplasm Clopton, Peabody and Keith reviewed the fact that the greater trochanter is developed as an epiphysis and deduced that as such, it is as susceptible to infection with tuberculosis as in any other epiphysis of the long bones, hence the probability of primary infection in the bone and secondary in the bursa adjacent to the trochanter

The bursa most commonly involved with tuberculosis is the large and constant trochanteric bursa beneath the gluteus maximus, although the subcutaneous bursa of the trochanter or any other bursa about the hip may also be involved by the spread of the infection Spalteholz described sixteen bursae in the region

1 Teale T P On the Simulation of Hip Disease by Suppuration of the Bursa over the Trochanter Major *Lancet* 2 506 507 (Oct.) 1870

of the hip, and other observers have described as many as thirty-one. Most of these are not constant and are small, the most important, however, are the gluteus maximus bursa over the greater trochanter, the iliopectineal bursa, and the ischiogluteal bursa. The first one lies between the gluteus maximus muscle and the posterior and lateral surface of the greater trochanter. The iliopectineal bursa is constant and large and is situated between the iliopsoas muscle and the iliofemoral ligament, it often is directly connected with the hip joint. Thus the importance of this bursa can readily be seen when one considers the possibility of spread of infection from the bursa into the hip joint, or vice versa. The ischiogluteal bursa is frequently present between the gluteus maximus muscle, the origin of the biceps and semitendinosus muscles, and the posterior surface of the tuberosity of the ischium.

The literature reveals that tuberculosis of the greater trochanter and the bursa over the trochanter starts usually in adolescence and that it is to be distinguished from disorders of the hip joint and neoplasms. It is apparently generally agreed that adequate treatment consists of radical excision of the diseased bursa and trochanter. The same cardinal points have been brought out in the study of our series of cases.

We selected a series of nineteen cases of disease of the trochanter from a large group, the diagnosis of which was verified by operation, pathologic examination and, in five cases, guinea-pig inoculation. The patients were ten men and nine women. The average age at the time of admission was 35. The oldest patient was 65 and the youngest 21. In most cases the disease started in the late teens and early twenties. The youngest age at onset was 9 years and the oldest 44.

The occupations of the patients apparently had no bearing on the etiology of the condition. There were six housewives, two carpenters, two laborers, three farmers, four office workers and one minister. Five of the patients gave a definite history of trauma about the trochanter preceding the appearance of symptoms, and two had been exposed to tuberculosis in their homes. Previous illnesses also appeared to have no bearing on the condition. One patient had been given a previous definite diagnosis of pulmonary tuberculosis, one of tuberculosis of the knee and one of the ankle.

The complaints on admission were mostly of pain and draining sinuses. Eleven patients complained of pain in the hip, usually mild that did not interfere with their daily routine. Six patients had pain referred to the front of the thigh and one patient to the knee. The pain of four patients was aggravated by lying on the affected side, of two by walking, and of two by sitting, standing and wet weather. Three of the patients had tumor of the hip and one each had osteomyelitis, sciatica and a stiffness of the hip, besides the pain. Some patients had more than one complaint, thus accounting for a larger number of complaints than patients. The duration of the complaint averaged eleven and one-half years, the longest was forty years and the shortest five weeks. It is possible that in the latter instance the complaint really started some time before it was brought to the patient's attention, as the condition usually starts insidiously, and often the patient is not aware of it until it is considerably advanced. The right side was affected in fourteen of the cases and the left in five. This may be another point indicative of trauma as an exciting or contributing etiologic factor, since the right side is more com-

monly injured than the left, whether or not the patient recalls an injury. In some cases we are confident that the disease was present and that the injury directed the patient's attention to it, two of the patients had sustained an injury and in a few days, within a period too short for tuberculosis to develop, had noticed swelling over the trochanter. Thus, in the four cases in which the time between the injury and the onset of the complaint was recorded, the time interval in one case was ten days and in one eight weeks, in the other two cases the interval was ten months and nine years.

The patients usually appeared healthy and were ambulatory. They complained of soreness and swelling about the hip which had existed for some time. Most of them (ten) had been operated on previously, the operation consisting only of incision for drainage. One patient was operated on five times, one four times, one twice and seven once. None of the patients had local heat or redness at any time, an important point to be kept in mind in making a differential diagnosis of disorders in the region of the hip joint.

Inspection readily disclosed distinct swelling over or posterior to the greater trochanter (fig 1). Cold fluctuating masses of varying size were noted on palpation.

Fig 1—A, anterior view showing tuberculosis of the greater trochanter involving the bursa; B, posterior view showing bulging area over the trochanter from tuberculosis of the bursa.

of this area. Five of the ten patients previously operated on had discharging sinuses, usually of serous material. The skin appeared normal locally in all cases, unless redness and discoloration appeared from application of heat. Motions of the hip, as a rule, were free, and weight bearing was painless. Pressure over the affected area, on the other hand, caused soreness. It has been noted also that in changing position, as in rising from a sitting position, the patient was conscious of pain, owing to muscular pull and stress in the region of the disease. Five patients had a slight limp. Blood pressure was normal in all but two cases in which there was hypertension. The temperature was slightly elevated in only two cases, and in the remainder it was normal on admission to the Mayo Clinic. The hemoglobin was practically normal in all cases and the leukocyte count averaged 8,700, the lowest count was 4,400 and the highest 12,800. The urinalysis and the Wassermann reaction of the blood were negative in all cases. For purposes of comparison and because of the possibility of lumbosacral and sacro-iliac involvement, the roentgenographic examination in these cases included the entire pelvis and both trochanters. In this series the roentgenograms showed the trochanters to be involved on the affected side in fifteen cases (79 per
